The critical question seems to be whether these outbreaks of respiratory mortality are the morbid results of the climatic changes alone, or whether pollution has added much to the lethal effects of the physical changes in the atmosphere In other words, is atmospheric pollution the modern equivalent of the *tertium quid* of the epidemiologists before Pasteur—something added to the epidemic situation between individuals and their climatic environment which produces respiratory illness? And if it is, is its effect purely immediate and transient precipitating acute illness or death in men already crippled by respiratory disease? Or does pollution have more chronic insidious effects in those exposed to it?

It should be confessed at once that these questions cannot yet be answered Correlations in time between factors so closely linked as temperature inversion and smoke pollution allow little discrimination between their separate effects But the primary role of epidemiology in the problems of medicine is reconnaissance rather than final resolution And to effect this, one must turn from chronology to a study of the geography of respiratory disease

Geographic Distribution of Respiratory Mortality

In his *Observations*, published in 1750, Short remarks about London that it is " more unhealthy (especially to Children and new Comers) from the Smoaks, Stinks, and close Air ", and elsewhere that " a very moist cold temperature of the Air certainly produces Heaviness, Coughs and other Disorders " It seems fitting that we in the London of today should try to bring Short up to date

The traditional approach to an epidemiological problem is by the analysis of mortality data In London the geographic pattern of respiratory mortality is certainly clear-cut, the death-rate from chronic bronchitis, for example, is more than twice as high in the districts to the north and east of the centre of the City than in other areas such as Hampstead, and Hewitt (1956) has given reasons for thinking that these disparities are due to atmospheric rather than social differences In the country as a whole, the areas of excessive chronic bronchitis mortality have been shown in studies by Pemberton and Goldberg (1954) and Daly (1954) to be those where indices of air pollution are highest These workers do not claim, however, that this is conclusive evidence of cause and effect Death is the terminal event in a chain of circumstances which may each be affected by urban conditions other than atmospheric pollution Thus the multiple contacts of city life may increase the frequency of the minor infections The worst-affected districts of our great towns may be the most heavily plagued by smoke, but they are equally the most congested areas, where men, whose jobs may subject them to industrial dusts, physical exhaustion, and climatic exposure, often live in overcrowded and inadequate homes Although our family studies rather suggest that some of these circumstances may be less important in respiratory infection than had been thought, other social factors such as diet or medical care and duration of convalescence may alter the case-fatality rate of those infections if not their frequency. Mortality-rates may not, therefore, reflect the unalloyed results of the single factor of air pollution, and geographical differences in death-rates should be interpreted with caution

Use of a Standard Occupational Group

An alternative gambit is afforded by the work of the Treasury Medical Service in supervising the health of Civil Servants of all kinds In the General Post Office, for example, postmen are uniformly selected, do much the same job at standard rates of pay, and, once established, form a relatively stable occupational group spending much of their working lives in the same district The cause and timing of all their sickness absences are meticulously recorded, and, should their working lives be cut short by serious disability, the medical standards for retirement on health grounds are continually under the scrutiny of the Treasury Medical Service staff

A review of wastage-rates among postmen due to premature retirement or death because of bronchitis and pneumonia showed a concentration in the great towns and industrial areas of the country There was no gradual increase from South to North such as one might expect if climate in general or temperature in particular were the dominating factors in morbidity Economic and occupational differences cannot explain this geographical pattern of morbidity Other factors to which postmen are exposed as citizens of the great industrial cities must therefore be the determinants of respiratory sickness, and the experience of this standard occupational group may give suggestive clues about their nature and numerical importance

We might consider, for example, that postmen on their rounds in the different parts of London are reasonably equal in all other material respects If so, we can use their sickness experience as an index, free from the influence of social background and occupation, of the effect of local environment on respiratory disease A Meteorological Office publication (Marshall 1952)—*A Century of London Weather*—assures us that there is little difference in temperature and humidity between places within the London area such as Kew, Kingsway, Croydon, and Greenwich, if anything it is warmer in the centre of London Yet the invaliding-rates from chronic bronchitis for London postmen rise steadily from south-west to north-east presenting the same concentration as the male mortality from bronchitis—and, incidentally, from cancer of the lung (Reid 1956, Stocks 1952) Wilkins (1954) reports that this concentration also coincides with the build-up of smoke in the Greater London area by the prevailing west-south-west wind

Thus encouraged, Dr Anthony Fairbairn and I (Fairbairn and Reid 1958) have tried, with the support of Dr W E Chiesman and his colleagues at the Treasury, to exploit the information on sickness among Civil Servants collected either routinely or by special sample surveys We hoped that the use of this standard population would control at least some of the variables involved without restricting unduly the relevance of our findings in these particular groups to the generality of the population

Local Levels of Presumptive Air Pollution and Bronchitis

Before the 1939–45 war, Durst (1940) organised a survey of atmospheric conditions at observation points scattered widely over the country Night and morning, observers noted the range of clear vision and classified conditions in their area according to the frequency and density of mist and fog Analysis showed that areas are quite consistent in their relative fogginess from one year to another Moreover, visibility indices of this type can be shown to be correlated with measures of pollution such as the sulphur-dioxide content of the air and indirect measures such as the index developed by Daly (1954) for county boroughs on the basis of coal consumption per acre of inhabited area.

The country can be divided into groups of areas where the postman's environment at work is fairly homogeneous—e.g., the towns and villages of East Anglia, Scotland outside Glasgow, or the industrial conurbation round Manchester. Wastage-rates due to premature retirement or death because of bronchitis and pneumonia were worked out on the basis of routine reports on such cases among the postmen working in thirty-seven such areas in the United Kingdom. A sample survey of sickness absence by cause allowed us to compute rates due to all forms of respiratory and other disease among these postmen and indoor workers of each sex in the same areas. From the information given in the Registrar-General's reports we calculated death-rates from bronchitis, pneumonia, pulmonary tuberculosis, and cancer of the lung among men and women aged 45–64 in the general population of the same thirty-seven areas. At the same time we collected data on other indices of local environment—population density and domestic overcrowding—likely to be relevant to the incidence of respiratory disease. All these observations related to periods round the 1951 Census.

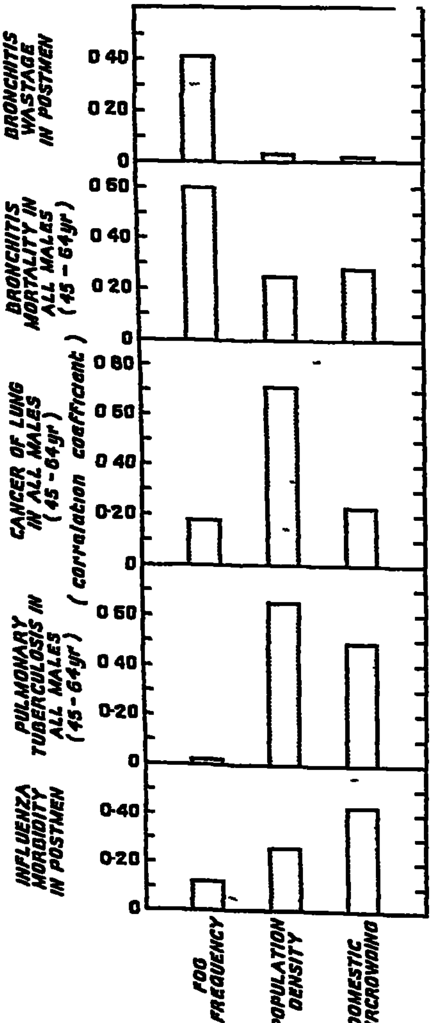

Fig. 5—Net correlation of respiratory disease experience and local environmental indices.

An analysis of the interrelations of some of these rates of respiratory sickness or death with the indices of local environment gave the results shown in fig. 5. The wastage-rates due to postmen dying or retiring prematurely because of bronchitis are uniquely and quite closely related to the frequency of thick and presumably polluted fog, but not to population density or domestic overcrowding, in the same area. An important feature of these results is the consistency between this pattern among men of the same occupational group throughout the country, and the behaviour of bronchitic mortality in middle-aged men in the population as a whole. Again, the death-rates in the general population from cancer of lung, and to some extent from pulmonary tuberculosis, are related not to fog frequency but to population density. This conformity in pattern between lung cancer and phthisis may be an expression of urban rural differences in cigarette smoking, which has been shown to be associated with death from both these diseases (Doll 1953, Lowe 1956). On the other hand, both pulmonary-tuberculosis mortality in the general population and influenza morbidity among postmen rise in step with the degree of domestic overcrowding in the areas, presumably as a result of increased opportunities for cross-infection in both these diseases. If this interpretation of these correlations is correct, it would seem that the regional distribution of bronchitis morbidity and mortality is more readily explained by local differences in fog frequency than by factors such as smoking habits or cross-infection which affect the incidence of lung cancer or pulmonary tuberculosis and other respiratory infections such as influenza.

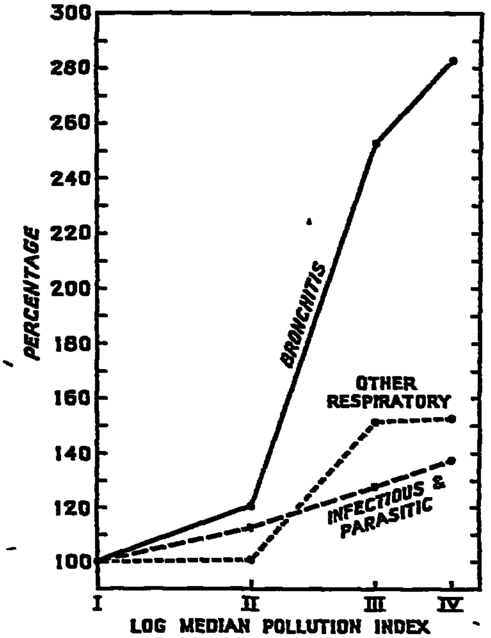

Fig. 6—Absence-rates among postmen working in areas with different air-pollution levels.

It seems reasonable, therefore, to regard the frequency of fog thick enough to restrict visibility to less than 1100 yards as a practical index of those atmospheric conditions which are related to high bronchitis sickness and death rates. But it would be less reasonable to assume that the relation was either simple or direct, for the gradient noted is largely one between small towns and major industrial cities, whose sickness experience may differ for other reasons than atmospheric pollution and in other ways than in the toll of chronic bronchitis.

A more detailed analysis of the sickness experience of postmen working in different areas can give some evidence on these points. The thirty-seven areas can be divided into groups, equal in the size of their postman population, but ranged in increasing steps of the fog index. The crude attack-rates among postmen in those groupings during the years 1946–53 inclusive for some major diagnostic catewith a rapid increase in air pollution, measured by the sulphur-dioxide content of the air, than with contemporary changes in temperature or humidity (Wilkins 1954)

The critical question seems to be whether these outbreaks of respiratory mortality are the morbid results of the climatic changes alone, or whether pollution has added much to the lethal effects of the physical changes in the atmosphere In other words, is atmospheric pollution the modern equivalent of the *tertium quid* of the epidemiologists before Pasteur—something added to the epidemic situation between individuals and their climatic environment which produces respiratory illness? And if it is, is its effect purely immediate and transient precipitating acute illness or death in men already crippled by respiratory disease? Or does pollution have more chronic insidious effects in those exposed to it?

It should be confessed at once that these questions cannot yet be answered Correlations in time between factors so closely linked as temperature inversion and smoke pollution allow little discrimination between their separate effects But the primary role of epidemiology in the problems of medicine is reconnaissance rather than final resolution And to effect this, one must turn from chronology to a study of the geography of respiratory disease

Geographic Distribution of Respiratory Mortality

In his *Observations*, published in 1750, Short remarks about London that it is " more unhealthy (especially to Children and new Comers) from the Smoaks, Stinks, and close Air ", and elsewhere that " a very moist cold temperature of the Air certainly produces Heaviness, Coughs and other Disorders " It seems fitting that we in the London of today should try to bring Short up to date

The traditional approach to an epidemiological problem is by the analysis of mortality data In London the geographic pattern of respiratory mortality is certainly clear-cut, the death-rate from chronic bronchitis, for example, is more than twice as high in the districts to the north and east of the centre of the City than in other areas such as Hampstead, and Hewitt (1956) has given reasons for thinking that these disparities are due to atmospheric rather than social differences In the country as a whole, the areas of excessive chronic bronchitis mortality have been shown in studies by Pemberton and Goldberg (1954) and Daly (1954) to be those where indices of air pollution are highest These workers do not claim, however, that this is conclusive evidence of cause and effect Death is the terminal event in a chain of circumstances which may each be affected by urban conditions other than atmospheric pollution Thus the multiple contacts of city life may increase the frequency of the minor infections The worst-affected districts of our great towns may be the most heavily plagued by smoke, but they are equally the most congested areas, where men, whose jobs may subject them to industrial dusts, physical exhaustion, and climatic exposure, often live in overcrowded and inadequate homes Although our family studies rather suggest that some of these circumstances may be less important in respiratory infection than had been thought, other social factors such as diet or medical care and duration of convalescence may alter the case-fatality rate of those infections if not their frequency Mortality-rates may not, therefore, reflect the unalloyed results of the single factor of air pollution, and geographical differences in death-rates should be interpreted with caution

Use of a Standard Occupational Group

An alternative gambit is afforded by the work of t Treasury Medical Service in supervising the health Civil Servants of all kinds In the General Post Office, f example, postmen are uniformly selected, do much t same job at standard rates of pay, and, once establishe form a relatively stable occupational group spending mu of their working lives in the same district The cause a timing of all their sickness absences are meticulous recorded, and, should their working lives be cut short b serious disability, the medical standards for retirement o health grounds are continually under the scrutiny of t Treasury Medical Service staff

A review of wastage-rates among postmen due to pr mature retirement or death because of bronchitis a pneumonia showed a concentration in the great towns a industrial areas of the country There was no gradu increase from South to North such as one might expe if climate in general or temperature in particular were t dominating factors in morbidity Economic and occupa tional differences cannot explain this geographical patte of morbidity Other factors to which postmen are expose as citizens of the great industrial cities must therefore b the determinants of respiratory sickness, and the exper ence of this standard occupational group may give sug gestive clues about their nature and numerical importanc

We might consider, for example, that postmen on the rounds in the different parts of London are reasonabl equal in all other material respects If so, we can use the sickness experience as an index, free from the influence o social background and occupation, of the effect of loc environment on respiratory disease A Meteorologic Office publication (Marshall 1952)—*A Century o London Weather*—assures us that there is little differenc in temperature and humidity between places within th London area such as Kew, Kingsway, Croydon, an Greenwich, if anything it is warmer in the centre o London Yet the invaliding-rates from chronic bronchit for London postmen rise steadily from south-west t north-east presenting the same concentration as the mal mortality from bronchitis—and, incidentally, from cance of the lung (Reid 1956, Stocks 1952) Wilkins (1954 reports that this concentration also coincides with th build-up of smoke in the Greater London area by th prevailing west-south-west wind

Thus encouraged, Dr Anthony Fairbairn and I (Fairbairn and Reid 1958) have tried, with the support of Dr W E Chiesman and his colleagues at the Treasury, to exploit the information on sickness among Civil Servants collected either routinely or by special sample surveys We hoped that the use of this standard population would control at least some of the variables involved without restricting unduly the relevance of our findings in these particular groups to the generality of th population

Local Levels of Presumptive Air Pollution and Bronchitis

Before the 1939–45 war, Durst (1940) organised a survey of atmospheric conditions at observation points scattered widely over the country Night and morning, observers noted the range of clear vision and classified conditions in their area according to the frequency and density of mist and fog Analysis showed that areas are quite consistent in their relative fogginess from one year to another Moreover, visibility indices of this type can be shown to be correlated with measures of pollution such ment and character of the disabling disease labelled as "chronic bronchitis" in postmen working in areas of differing degrees of pollution

A comparison of the frequency and severity of attacks of bronchitis during the working lives of bronchitic invalids and their matched controls showed that, even in early adult life, those destined to become disabled by chronic bronchitis have more and longer absences from this cause than other men of the same age (Reid and Fairbairn 1958) The same general trend is equally apparent in the frequency of absence due to colds and other upper respiratory infections, and there is evidence among these bronchitic invalids of a minority who manifest an unusual susceptibility to respiratory infection at least twenty years before they die or have to stop work (usually in their middle fifties) If this long-term predisposition to respiratory illness extends back, as seems likely, to earlier childhood, then in chronic bronchitis, as in so much else, the child is father to the man

Regional Variations in Natural History

Age-trends in both sickness-absence and death-rates from chronic bronchitis agree in emphasising the rapid deterioration which sets in after the age of 45, and fig 8 suggests that the speed of disease evolution may be related to local levels in presumptive air pollution A more detailed comparison of the frequency, duration, and complications of attacks of respiratory illness among these bronchitic postmen showed that, after 45, men working in the more heavily polluted districts of the country had more frequent absences from work and lost more time over the year than did their colleagues in the less affected areas Although the overall incidence of minor and major respiratory infections may not be very different, the attack-rate of pneumonia and pleurisy is 30% higher in the critical age group of 45–54 in the more heavily polluted districts

Reviewing this pattern of respiratory disease makes it seem likely that the exposure to minor infection is not very different in the four groups of areas, but that the cumulative effect of atmospheric pollution transmutes minor infections in later life into major illnesses which appear as serious colds, bronchitis, pleurisy, or pneumonia Of perhaps greater moment, however, are the disorders of circulation which appear, under various diagnostic labels such as "hypertension" or "myocarditis", as complications in the downward course of cardiorespiratory disease among these postmen The serious prognostic significance of these illnesses is evident in the consistent rise in the proportion of men dying in the service while still on sick-leave This immediate case-fatality rate rises steadily from 3% in the least to 11% in the most heavily polluted areas, and the expectation of life of those who retire on pensions after invaliding is appreciably shorter in these foggy districts of the country

To recapitulate—we have found that in a stable group of men, doing the same job for the same pay under the same conditions of service, there are wide geographic variations in the incidence of disabling respiratory disease These variations cannot be explained by social, economic, or occupational factors or by any consistent difference in climate other than fog Not only do more postmen become disabled by chronic bronchitis in areas where thick and presumably polluted fog is more frequent, but the character and natural history of the disease in these areas reflects variation in atmospheric pollution In the most heavily polluted areas of the country—mainly the industrial cities—minor infections among younger bronchitics do not appear to be much more frequent than elsewhere But among the older bronchitic postmen in polluted areas, these minor infections lead to more frequence absence from work and seem more often to lead on to complications such as pleurisy, pneumonia, and circulatory failure which hasten death

Smoking Habit as a Complicating Factor

One of the most striking features of mortality from chronic bronchitis in this country is the pronounced male excess in middle life This excess might be attributed to the occupational circumstances of men's lives, which may expose them to the weather, to hard physical exertion, or to many sources of infection Again, these differences apparent in mortality may reflect differences in case-fatality rate rather than in disease incidence In the Civil Service, however, we have men and women working side by side in the same offices doing the same job and exposed, at least through their working hours, to the same environmental conditions Comparison of attack-rates calculated for men and women indoor office workers in different age-groups but all exposed to the fairly uniform climate of London showed that the excessive mortality of the male is paralleled by an increased morbidity-rate in middle life which cannot be explained by differences in occupation between the sexes (Reid 1956), and Higgins (1957) has reported a similar male excess in the prevalence of bronchitic symptoms in a country district

The differing clinical responses of fathers and mothers to infection noted in the Paddington survey (Brimblecombe et al 1958) certainly suggested that in early adult life the female is more susceptible to respiratory infection than the male The opposite could conceivably hold in later life, but, as Oswald and Medvei (1955) have shown in the same occupational group of Civil Service clerks, the sex disparity is more likely to be explained in part by differences in smoking habits In the longitudinal study already described, there was evidence in the sickness records and death certificates of men followed up for some years of an excessive incidence of peptic ulcer, cancer of the lung, and coronary thrombosis—all conditions already linked by numerous studies with cigarette smoking When taken together with the more direct evidence produced by Doll and Hill (1956) on the consistent upward trend with increased cigarette consumption among doctors in mortality from chronic bronchitis, these results must increase suspicions about the aggravating effect of cigarette smoking in chronic bronchitis and the importance of differences in smoking habits as a source of local variation in mortality from this disease

Prospect for Research

Arnott (1954), speaking as a clinician, has generously referred to the extension of the epidemiological approach beyond the infectious fevers as "the most exciting feature of current medical science" I should like to believe that this was so, but I must admit to the charge that epidemiological studies are apt to raise more questions than they answer The pilot work I have described establishes no more than a prima-facie case for further study of the undoubted association between sickness and death from chronic bronchitis and the frequency of dense and presumably polluted fog in the same area It would be premature to revive the penalty imposed on a citizen of Southwark in the year 1370 who was indicted for "causing a filthy and fulginous vapour by burning raw coal" (He was

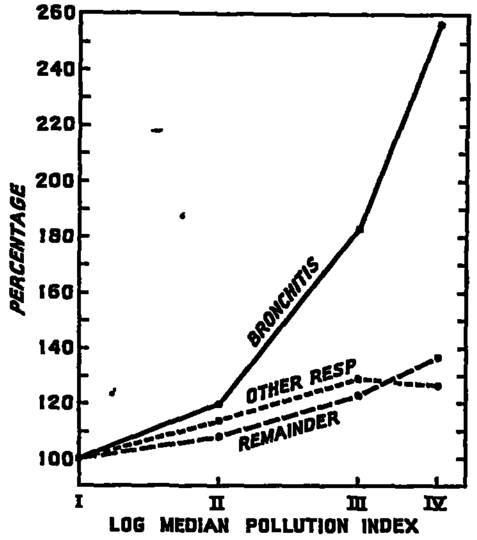

Fig 7—Ratios of absence-rates for postmen and clerks according to local levels of air pollution

gories are set out in fig 6 The gradient between the fog group rates (expressed as ratios to the basic level in the least foggy areas) is much more distinct for bronchitis than for all other respiratory diseases

Although there is a rise in the incidence of the group of specific infectious and parasitic diseases, it is hardly great enough to suggest that a generally increased opportunity for infection in the larger towns fully explains the high bronchitis-rates there There is also some reason to believe that lower morale in the larger post offices may be reflected in higher sickness-rates, but there seems to be no very good reason why chronic bronchitis should be consistently singled out as the excuse for unwarranted absence only in the fog-ridden areas

The most convincing evidence that the excessive chronic-bronchitis rate in the industrial centres is not an illusory reflection of morale but a substantial physical phenomenon comes from a comparison of the experience of postmen and clerks or of postmen of different ages working in the various regions of the country Because of the differing physical demands of their jobs, the same degree of disability due to sickness or injury must inevitably incapacitate the postman more than the clerk Even if the incidence of chronic bronchitis were exactly the same in these two occupational groups, some difference in the frequency of absence from work for that cause would be expected On the other hand, both groups face the infective risk and psychological background common to all inhabitants of the same area If, then, regional variations in air pollution played no part in the onset of bronchitis, this relative disparity between the attack-rates among postmen working largely out of doors and clerks working inside should be the same all over the country When, however, the absence-rates attributed to chronic bronchitis for postmen are compared as a ratio to those of clerks in each of the four pollution groups in turn (fig 7), it becomes quite clear that the gap between the rates widens with each increase in the index of pollution There is no such steep gradient either for other respiratory diseases or for all the remaining causes of absence In short, the increasing frequency of smog is associated with relatively more frequent attacks of bronchitis among the postmen, who are more exposed by their active outside job to that polluted atmosphere, than among the sheltered indoor clerks

What may be the cumulative effects of differences i exposure to polluted atmosphere also appears in the age specific attack-rates of chronic bronchitis among postme of the same age but working in the four pollution group of areas Beginning as early as the age-group 25–34, th gap between the age-specific rates widens increasingl with age Atmospheric pollution may thus have som initiating or persistently aggravating effect on chron bronchitis quite apart from its action on the cardiac o respiratory cripple in the acute smog episode In New Zealand Eastcott (1956) showed that immigrants from thi country who had lived here for the first thirty years o life had higher death-rates from cancer of the lung tha the New Zealand born population of British stock, and the increasing gap in bronchitic incidence here observe may be another result of prolonged exposure to Britis conditions—among them the atmosphere of British towns

Evolution of Chronic Bronchitis

Up to this point I have taken cross-sectional snapsho of the sickness experience of men of different ages durin a relatively short period Chronic bronchitis, however, i a disease whose often slow progress must be studied as i develops over the life-time of the individual Longi- tudinal records of this kind covering the whole of life ar seldom, if ever, available, but in the Post Office each man's detailed sickness history over his entire service is kept i his personal file Thus it was possible to compare the sickness experience of postmen who had been invalided from the postal service because of chronic bronchitis or who had died prematurely because of that disease with that o matched " controls " These " controls " were other postmen, randomly selected from those of the same age, working from the same office, but without completely disabling respiratory disease The intention was to see how the natural history of respiratory illness during adult life o men ultimately disabled by bronchitis differed from the frequency and nature of respiratory illness of other men, not so disabled, working in the same environment At the same time, it should be possible to contrast the develop-

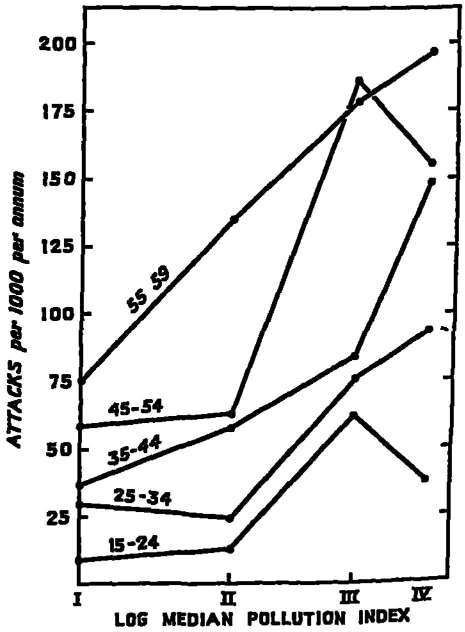

Fig 8—Bronchitis absence-rates at different ages for postmen in areas with different air-pollution levels

ment and character of the disabling disease labelled as "chronic bronchitis" in postmen working in areas of differing degrees of pollution.

A comparison of the frequency and severity of attacks of bronchitis during the working lives of bronchitic invalids and their matched controls showed that, even in early adult life, those destined to become disabled by chronic bronchitis have more and longer absences from this cause than other men of the same age (Reid and Fairbairn 1958). The same general trend is equally apparent in the frequency of absence due to colds and other upper respiratory infections, and there is evidence among these bronchitic invalids of a minority who manifest an unusual susceptibility to respiratory infection at least twenty years before they die or have to stop work (usually in their middle fifties). If this long-term predisposition to respiratory illness extends back, as seems likely, to earlier childhood, then in chronic bronchitis, as in so much else, the child is father to the man.

Regional Variations in Natural History

Age-trends in both sickness-absence and death-rates from chronic bronchitis agree in emphasising the rapid deterioration which sets in after the age of 45, and fig. 8 suggests that the speed of disease evolution may be related to local levels in presumptive air pollution. A more detailed comparison of the frequency, duration, and complications of attacks of respiratory illness among these bronchitic postmen showed that, after 45, men working in the more heavily polluted districts of the country had more frequent absences from work and lost more time over the year than did their colleagues in the less affected areas. Although the overall incidence of minor and major respiratory infections may not be very different, the attack-rate of pneumonia and pleurisy is 30% higher in the critical age group of 45–54 in the more heavily polluted districts.

Reviewing this pattern of respiratory disease makes it seem likely that the exposure to minor infection is not very different in the four groups of areas, but that the cumulative effect of atmospheric pollution transmutes minor infections in later life into major illnesses which appear as serious colds, bronchitis, pleurisy, or pneumonia. Of perhaps greater moment, however, are the disorders of circulation which appear, under various diagnostic labels such as "hypertension" or "myocarditis", as complications in the downward course of cardiorespiratory disease among these postmen. The serious prognostic significance of these illnesses is evident in the consistent rise in the proportion of men dying in the service while still on sick-leave. This immediate case-fatality rate rises steadily from 3% in the least to 11% in the most heavily polluted areas, and the expectation of life of those who retire on pensions after invaliding is appreciably shorter in these foggy districts of the country.

To recapitulate—we have found that in a stable group of men, doing the same job for the same pay under the same conditions of service, there are wide geographic variations in the incidence of disabling respiratory disease. These variations cannot be explained by social, economic, or occupational factors or by any consistent difference in climate other than fog. Not only do more postmen become disabled by chronic bronchitis in areas where thick and presumably polluted fog is more frequent, but the character and natural history of the disease in these areas reflects variation in atmospheric pollution. In the most heavily polluted areas of the country—mainly the industrial cities—minor infections among younger bronchitics do not appear to be much more frequent than elsewhere. But among the older bronchitic postmen in polluted areas, these minor infections lead to more frequence absence from work and seem more often to lead on to complications such as pleurisy, pneumonia, and circulatory failure which hasten death.

Smoking Habit as a Complicating Factor

One of the most striking features of mortality from chronic bronchitis in this country is the pronounced male excess in middle life. This excess might be attributed to the occupational circumstances of men's lives, which may expose them to the weather, to hard physical exertion, or to many sources of infection. Again, these differences apparent in mortality may reflect differences in case-fatality rate rather than in disease incidence. In the Civil Service, however, we have men and women working side by side in the same offices doing the same job and exposed, at least through their working hours, to the same environmental conditions. Comparison of attack-rates calculated for men and women indoor office workers in different age-groups but all exposed to the fairly uniform climate of London showed that the excessive mortality of the male is paralleled by an increased morbidity-rate in middle life which cannot be explained by differences in occupation between the sexes (Reid 1956), and Higgins (1957) has reported a similar male excess in the prevalence of bronchitic symptoms in a country district.

The differing clinical responses of fathers and mothers to infection noted in the Paddington survey (Brimblecombe et al. 1958) certainly suggested that in early adult life the female is more susceptible to respiratory infection than the male. The opposite could conceivably hold in later life, but, as Oswald and Medvei (1955) have shown in the same occupational group of Civil Service clerks, the sex disparity is more likely to be explained in part by differences in smoking habits. In the longitudinal study already described, there was evidence in the sickness records and death certificates of men followed up for some years of an excessive incidence of peptic ulcer, cancer of the lung, and coronary thrombosis—all conditions already linked by numerous studies with cigarette smoking. When taken together with the more direct evidence produced by Doll and Hill (1956) on the consistent upward trend with increased cigarette consumption among doctors in mortality from chronic bronchitis, these results must increase suspicions about the aggravating effect of cigarette smoking in chronic bronchitis and the importance of differences in smoking habits as a source of local variation in mortality from this disease.

Prospect for Research

Arnott (1954), speaking as a clinician, has generously referred to the extension of the epidemiological approach beyond the infectious fevers as "the most exciting feature of current medical science". I should like to believe that this was so, but I must admit to the charge that epidemiological studies are apt to raise more questions than they answer. The pilot work I have described establishes no more than a prima-facie case for further study of the undoubted association between sickness and death from chronic bronchitis and the frequency of dense and presumably polluted fog in the same area. It would be premature to revive the penalty imposed on a citizen of Southwark in the year 1370 who was indicted for "causing a filthy and fulginous vapour by burning raw coal". (He was hanged) On the other hand, the human and economic consequences of neglect of the environment in the problem of chronic bronchitis are such that any lead, however tenuous, must be followed up

Measurement and comparison are at the basis of epidemiology, and improved nosography is the first step in that splitting of the problem into manageable parts which is essential to its solution Vital statistics deal with chronic bronchitis as a single clinical entity, yet the bronchitis of the young female in a country district may be an allergic response quite different from the infective, rapidly progessive, and disabling disease of the older male in the polluted and congested city The evidence from the study of the invalid postmen certainly suggests that one or more factors in urban environment or habits do twist the clinical pattern into something different and more lethal The classification of respiratory disorders and the standardisation of diagnostic criteria are clearly first needs for any intelligent comparison of experience in different countries and even in different parts of the same town

If we discount the uncontrollable elements of our island climate such as sudden changes of temperature and humidity, we must still identify the hazardous element in the polluted fog of industrial cities If the operation of the Clean Air Act succeeds in removing the solid content of city smoke, will any remaining sulphurous and other gaseous elements continue the erosion of the bronchi of the next generation? Perhaps we must wait, but we should also watch

Although the enhanced risks of infection in the crowded towns cannot explain more than part of the excessive morbidity and mortality from chronic bronchitis, pollution may aggravate infection to produce a much more complex and crippling disease The analogy of the coaction of dust and tuberculous infection in progressive massive fibrosis in miners is apposite, and the methods of field study which are proving so profitable in that condition should be employed in a much wider study of the nature of chest disease following different exposures to atmospheric pollutants

Air pollution produced by burning raw coal is not, however, the only external factor likely to be involved in chronic bronchitis Quite apart from the specific occupational hazards, which I have not discussed, differences in personal smoking habits may explain some of the disparity between town and country and more of the difference between the middle-aged male and female We thus need precise sample surveys of the smoking habits of men and women doing the same job in town and country to see whether, for example, the prevalence of chronic bronchitis is the same in men and women non-smokers living in the same environment Again, cigarette smokers in the fog-ridden towns may have the unduly high bronchitis-rates which some cumulative synergism of personal and atmospheric smoke pollution might produce This is the sort of question which can be answered only by surveys and long-term follow-up

In presenting this catalogue of uncertainties, I am quite unabashed by the dismissal of some earnest students of geology by Sir Joseph Banks, the one-time despotic president of the Royal Society They asked his leave to circulate a series of questions of moment His curt response was that a few fools could ask more questions in half an hour than wise men might answer in years

On the contrary, I prefer to draw courage from Sir William Gull's advice to the British Medical Association on the conduct of collective investigations "Nature is very much a Sphinx," he said, "and will answer no question put to her if it be open to evasion" He counselled the committee to put "a definite question, and that being settled, follow it up by another, and so on i series Nature must at last be driven into a corner and b obliged to say 'Yes' or 'No'" That seems to me to b the only course open to us through the maze of chroni respiratory disease, for I am at one with Gull in believin that a question well posed is already half answered

HÆMOPHILIA-LIKE STATES IN GIRLS *

ARMAND J QUICK
Ph D Illinois, M D Cornell
PROFESSOR OF BIOCHEMISTRY AND DIRECTOR OF THE DEPARTMENT

CLARA V HUSSEY
M S Marquette
INSTRUCTOR IN BIOCHEMISTRY

From the Marquette University School of Medicine, Milwaukee, Wisconsin

THE possibility that a female hæmophilic offspring might result when an ovum carrying the recessive hæmophilic gene in the X chromosome is fertilised by a sperm also containing the defective gene in its X chromosome was pointed out by Piney (1927) No authentic case, however, was found in the extensive and numerous pedigrees collected by Bulloch and Fildes (1911), Birch (1937), and others

When Hutt et al (1948) discovered in a dog a bleeding condition which appeared identical with the human disease, it became possible to test experimentally whether hæmophilia could be produced in the female An affirmative answer was obtained by Graham et al (1949) when they produced female hæmophilic pups by mating a carrier bitch with a hæmophilic male The human counterpart, a female bleeder having a carrier mother and a hæmophilic father, was reported by Israels et al (1951), their patient exhibited the clinical history and the laboratory findings of hæmophilia

---

* This work was supported by a grant from the National Heart Institute, National Institutes of Health, United States Public Health Service

The recent discovery of several types of hæmophilia-like states necessitates reassessment of classical hæmophilia and its related states in women The opportunity of having available for repeated studies several girls with bleeding conditions closely resembling hæmophilia made it possible to obtain additional pertinent information and to permit correlation with published cases

Laboratory Procedures

The details of the procedures used have been described recently (Quick 1957a) Only a few comments, therefore, on the techniques and interpretation will be given here Blood collected with a silicone-coated syringe and needle was transferred to test-tubes similarly coated The tubes were immersed in an ice-bath. All clotting-tests were made in glass test-tubes (13 mm × 100 mm) at 37°C

Whole-blood clotting-time —This test was made, whenever possible, immediately after the blood was collected, because storage of blood in silicone-coated tubes shortens the clotting-time The normal range is 5-10 minutes

Prothrombin-consumption time —By allowing blood to clot under standardised conditions and by determining the prothrombin activity of the serum the thromboplastin generated during clotting is indirectly measured Since the test is empirical, meticulous standardisation is essential

The test-tube containing 1 ml of blood was put in a water-bath at 37 C Exactly 15 minutes after a solid clot had formed the tube was centrifuged and reincubated at 37°C for 45 minutes more The prothrombin time of the serum was determined by blowing 0 1 ml into a mixture of 0·1 ml of rabbit-brain thromboplastin, 0 1 ml of 0 02*M* $CaCl_2$, and 0 1 ml of deprothrombinised oxalated rabbit-plasma, and accurately timing the clotting Since serum lacks fibrinogen and labile factor (factor v), these have to be supplied, rabbit-plasma adsorbed with $Ca_3(PO_4)$ is a satisfactory source of both Neither deprothrombinised human plasma nor fibrinogen solution is satisfactory, because they do not supply sufficient labile factor When the consumption of prothrombin is very low, as in the clotting of blood from a patient with severe hæmophilia or of platelet-depleted plasma, the prothrombin time of the serum is 8 or 9 seconds

This procedure has been designated " basic " to distinguish it from the following modified prothrombin-consumption time tests which measure various thromboplastin precursors more specifically

Thromboplastinogen-activity time —When rabbit-brain extract is heated to 60°C it loses its holothromboplastic potency—i e , it no longer brings about consumption of prothrombin when added to hæmophilic blood (Quick et al 1952) It retains, however, an activity which is similar to that of platelets it causes consumption of prothrombin in normal plasma depleted of platelets but not in hæmophilic plasma A low consumption of prothrombin with this test is observed in both hæmophilias, A and B, but a normal result is obtained in thrombocytopenic purpura and thrombasthenia (Quick 1957b) In making the test 0 025 ml of the rabbit-brain extract heated to 60°C is added to 1·0 ml of blood Except for this step, the procedure is the same as in the basic test

Hæmolysate test —An extract of human erythrocytes has an activity similar to but not identical with that of platelets (Quick et al 1954b) Added to normal platelet-poor plasma it causes a significantly greater consumption of prothrombin than does an extract of platelets Mixed with plasma from a patient with severe hæmophilia it causes no detectable consumption of prothrombin, shown by the minimal serum-prothrombin time of 8 or 9 seconds The addition of minute amounts of a purified preparation of thromboplastinogen or of normal plasma to hæmophilic blood brings about a relatively high consumption of prothrombin By this test the effect of adding 1 part of normal plasma to 1000 parts of hæmophilic plasma can be measured quantitatively (Quick 1957c)

Consumption of prothrombin with added aged normal serum —The addition of 0 1 ml of aged normal serum to 1 ml of hæmophilic blood before clotting causes no improvement in the consumption of prothrombin On the contrary, when aged serum is added to blood from a patient with hæmophilia B, the consumption of prothrombin is strikingly increased (Quick 1957c)

Thromboplastin-generation test —The method of Biggs and Douglas (1953) was used, but modified by using a platelet substitute made according to the method of Bell and Alton (1954) In recording the results the shortest clotting-time was selected The normal range is usually 7–12 seconds

Preparation of thromboplastinogen —The method described by Quick et al (1954a) was used It consists in removing platelets by rapid centrifugation, then adsorbing prothrombin, stable factor, and PTC (Christmas factor) with $Ca_3(PO_4)_2$, and precipitating the active principle by dilution with ice-cold distilled water and saturation with CO_2 The product obtained is highly potent and free from the other known clotting factors, except for traces of labile factor and fibrinogen The agent has been named thromboplastinogen (Quick 1947) in preference to antihæmophilic globulin, the term originally applied to a plasma factor whose activity was postulated to be independent of platelets (Lozner et al 1942) It was pointed out that the factor could also be named prothromboplastin, but that thromboplastinogen was " more euphonious "

Case-reports

Case 1 —A girl born on Sept 29, 1947, was noted to bruise easily in early infancy, but her first serious bleeding occurred at the age of 18 months, when she cut the frenum of her upper lip At 3 years she had a large hæmatoma on the medial aspect of her left thigh and a swollen knee She required several transfusions but was in hospital only six days Dr M H Poindexter, Jr , of Fargo, North Dakota, diagnosed hæmophilia on the basis of a normal prothrombin time and a prolonged clotting-time

These findings were confirmed in August, 1953, when, in addition, a very poor consumption of prothrombin was found No correction was observed when the patient's blood was mixed with that of a known hæmophiliac Physical examination was normal except for old ecchymotic spots, a hæmatoma on her right elbow, and swelling of the sole of her right foot.

On her second visit, in May, 1954, the laboratory results were the same as before, and the only findings on physical examination were the characteristic small hæmatomas and bruises The patient was not seen again until July, 1956 Between her second and third visits she had swelling of her left popliteal area, a wrist, and an ankle The last named prevented her for several days from walking In August, 1954, she had seven teeth extracted Although she was given one transfusion before and one after the extractions, bleeding began on the fourth day and required six transfusions to control She has not had any transfusions since this episode but has had intramuscular bleeding into a thigh, and in November, 1957, an entire arm became swollen after an injury to the elbow

She was last seen in January, 1958, when her blood was extensively studied, and the same tests were run simultaneously on the blood of a patient known to have severe hæmophilia No deformity, enlargement, or limitation of movement of any joint was found , but, when her right knee was flexed, a sharp click was constantly heard True hæmarthrosis was not shown on radiography Most of the severe bleeding was intramuscular, there was neither epistaxis nor hæmaturia

The family history is entirely negative The mother has no tendency to bleed, two brothers and one sister are normal Neither her father nor her mother knows of any bleeding in their families The patient's father, likewise, is entirely normal, and he has three brothers who have no tendency to bleed Especially significant, the patient has a brother three years younger who is entirely normal

The laboratory studies are summarised in tables I–III

Case 2 —This girl was born on June 16, 1949 Since her early history has been published previously (Quick and Hussey 1953a), only the salient facts need be given here Easy bruising was noted at the age of 5 months At the age of 15 months she had swelling of a knee, and a month later of her buttocks At the age of 3 years she had swelling in the calf of her left leg, severe enough to prevent her for several days from walking Later she had pain and swelling of an ankle She was seen by us for the first time in November, 1951, when she had a hæmatoma on her forehead The main laboratory findings were normal clotting- and bleeding-times, a slightly prolonged prothrombin-time (16 seconds), and a very defective prothrombin-consumption time On mixing her blood with that of a patient known to have severe hæmophilia no correction was observed with the prothrombin-consumption test

TABLE I—LABORATORY FINDINGS IN CASE 1 AND FAMILY

Test	Case 1	Brother	Father	Mother	Known hæmophiliac	Normal control

Subject's plasma	47	9	9	8	51	7
Subject's serum	9	8	7	7	8	7

Studies on patient's brother, father, and mother were made in 1956
Bleeding and prothrombin times were normal in all subjects
* Thromboplastinogen-activity time

The second studies were made in September, 1952, when her parents and brother were also studied Her findings were exactly the same as those obtained a year previously Significantly, both her father and her mother had a slightly prolonged prothrombin-time—$13^{1}/_{2}$ and 13 seconds respectively At this time mixing her blood with that of a hæmophiliac caused some correction

The patient was seen again in July, 1956 During the five-year interval she had a few serious episodes of bleeding She bled for $2^{1}/_{2}$ weeks after the extraction of a tooth She was given one transfusion, which so far has been the only one received Easy bruising continued and appeared to be worse after colds Her ankles occasionally became swollen She had mild epistaxes for 2 weeks On physical examination typical ecchymotic spots with a hard central nodule were found All her joints were normal in size and function

Her family history is entirely negative No tendency to bleed was found in either the father's or the mother's family Two brothers of the patient are well, have never had abnormal bleeding, and have not shown any tendency to hæmorrhage

TABLE II—EFFECT OF MIXING CASE 1'S BLOOD WITH NORMAL AND WITH HÆMOPHILIC BLOOD

Blood	Clotting-time (min)	Prothrombin-consumption time (sec)	
		Basic	With hæmolysate added
Case 1	51	8	8

Normal control	8	32	93
Case 1+known hæmophiliac*	24	8	8
Case 1+normal control	$5^{1}/_{2}$	28	77
Known hæmophiliac+normal control	6	22	100

* Equal volumes were mixed

The results of laboratory studies are shown in tables IV–VI

Case 3—This girl was born on Aug 7, 1947 She bruised easily but had no serious bleeding until the age of 18 months She was then seen by a physician because of an eye infection Purpura was diagnosed, probably because of numerous ecchymoses Without any apparent cause she had a cerebral hæmorrhage She was in coma and later was paralysed but recovered fairly rapidly During her early childhood she had numerous bleedings from mucosæ, particularly from the gums, throat, and nose To control epistaxis she required at times several transfusions She also had intramuscular bleeding At the age of 6 years she injured her abdomen and a leg in a fall An extensive hæmorrhage involving the knee and calf resulted immediately, later she had sharp crampy abdominal pain After this had subsided she was symptomless for 11 days, when she had gross hæmaturia and epistaxis At the age of 8 years she had a gastrointestinal infection which caused severe bleeding, both hæmatemesis and melæna, five transfusions were given The episodes of bleeding have continued but have become somewhat less frequent Epistaxis and subcutaneous and intramuscular hæmorrhage remain her most common forms of bleeding During her first 10 years of life she received more than two hundred transfusions Trivial injuries often caused serious hæmorrhage Recently she bled into the palm of her hand, causing enough pressure on the ulnar and median nerves to produce serious motor and sensory disturbances In spite of her difficulties she leads a surprisingly normal life, attends school, and keeps up well with her studies She has no ankylosis or joint deformities and no abnormal neurological signs

From the family history it can be deduced that the disease is hereditary She has a brother two years younger who bleeds like her Another brother two years older is clinically entirely normal Neither father nor mother has had abnormal bleeding, and they know of no bleeding in their families

The patient, her brother who bleeds, and the rest of the family have been studied six times since 1953 The results of various tests have remained fairly constant, except the thromboplastin-generation test, which varies, especially in the activity of the serum The data of two recent studies are presented in table VII

TABLE III—EFFECT OF ADDING PURIFIED THROMBOPLASTINOGEN TO PLASMAS OF CASE 1 AND OF KNOWN HAEMOPHILIACS

Subject	*Amount of* thromboplastinogen (ml) added to 1 0 ml of plasma*	Clotting-time (*min*)	*Modified* prothrombin consumption time† (sec.)
Case I	0		8

* The native plasma stored in silicone-coated tubes at −20°C was used, which fact explains the short clotting-times
† In addition to the thromboplastinogen 0 1 ml of hæmolysate and 0 001 ml. of aged serum were added to 1 0 ml of plasma
‡ This amount was obtained from 0 05 ml of normal human plasma

Case 4—This girl was born on Oct 25, 1952 Her first serious bleeding was at the age of 9 months, when she cut a lip During the first years of life her growth and weight gain were low, but otherwise she was normal except for bleeding She bruises easily, has bled from her throat, and had hæmatemesis following a blow to her abdomen

Her family history is entirely negative She has a brother older than she and one younger, both are entirely normal Her father and mother have never had abnormal bleeding, and their families have no record of bleeders

The patient and her parents were only studied once The data are recorded in table VIII

Results

Case 1

The laboratory findings in case 1 are identical with those obtainable in true hæmophilia of the severest type (table I) No consumption of prothrombin can be demonstrated even with as sensitive a procedure as the hæmolysate test The lack of correction in the consumption of prothrombin, when aged normal serum is added to the blood before clotting, localises the defect in the plasma, this localisation is confirmed by the thromboplastin-generation test The close similarity between the

,, + ,, no. 3	14

patient's and hæmophilic blood is further shown by the lack of mutual correction when the two bloods are mixed, no consumption of prothrombin can be demonstrated even when hæmolysate is added before clotting (table II). When either the patient's or hæmophilic blood is mixed with normal blood, a significant correction takes place, measured by the prothrombin-consumption test, and the effect is quantitatively about the same. The strongest evidence known for concluding that the coagulation defect in the patient's blood is identical with that in true hæmophilic blood is the correction effected by adding even a minute amount of a purified preparation of thromboplastinogen to her blood. It will be observed from table III that 0·005 ml. of the preparation obtained from 0·05 ml. of normal plasma, when mixed with 1·0 ml. of her native plasma, increased the prothrombin consumption from 8 to 37 seconds. This correction corresponds quantitatively to that obtained when the same amount is added to hæmophilic plasma.

As in true hæmophilia the girl's bleeding-time, prothrombin-time, and platelet-count are normal. Her clinical history, likewise, corresponds to that usually obtained in classical hæmophilia. Epistaxis and other types of mucosal bleeding are absent or infrequent, whereas deep intramuscular hæmorrhages almost invariably follow injury, unless aborted by such means as cold and pressure. On the basis of the much prolonged clotting-time and the almost complete absence of prothrombin consumption, she should be classed as having severe hæmophilia. Her tendency to bleed has remained relatively mild. Although one may conclude from the history that she has had hæmarthroses, no permanent injury has been done to any joint.

TABLE VI—EFFECT OF LABILE AND STABLE FACTORS ON CASE 2'S PROTHROMBIN-TIME

Plasma	Prothrombin-time (sec.)
Case 2	16
Case 2 + labile factor*	15
Case 2 + aged serum†	11
Normal control	11½
Case 2 + normal control (1 : 1)	11

* 0·01 ml. of rabbit plasma adsorbed with Ca₃(PO₄)₂ added to 0·1 ml. of case 2's plasma.
† 0·01 normal aged serum added to 0·1 ml. of case 2's plasma.

Case 2

The laboratory findings in case 2 (table IV) are strikingly different from those in case 1. The clotting-time is only slightly prolonged, but the prothrombin-time is definitely prolonged. The prothrombin-consumption time and the thromboplastinogen-activity time are as abnormal as in mild hæmophilia. The addition of either hæmolysate or normal aged serum to the blood before clotting brings about normal consumption of prothrombin. The generation of thromboplastin, measured by the test of Biggs and Douglas (1953), is strikingly low, and the defect is in the serum. On mixing her native plasma with the plasma of a known hæmophiliac a mutual correction is obtained (table V). Her prothrombin-time appears to be fixed at 15 or 16 seconds, it is not shortened by adding labile factor but is corrected by adding aged normal serum. When an equal volume of her plasma is mixed with fresh normal plasma, the mixture has a normal prothrombin-time (table VI).

TABLE VIII—LABORATORY RESULTS IN CASE 4 AND HER PARENTS

Test	Case 4	Father	Mother
Clotting-time (min.)	8	8	5½
Prothrombin-time (sec.)	12	11½	11½
Bleeding-time (min.)	30–		
Prothrombin-consumption time (sec.)			
Basic	12½	21	20
With T.A.T. reagent	12½	22	42
With hæmolysate	12	77	135
With serum	13	22	20
Thromboplastin-generation test (sec.)			
Subject's plasma	39	11	11½
Subject's serum	7	7	9

From the data in table IV it may be observed that both her parents and two brothers show abnormalities. All have a slightly prolonged prothrombin-time except the father, but he has shown this abnormality at other times. The abnormality is best shown by the thromboplastin-generation test. Interestingly, her youngest brother has a thromboplastin-generation time which is even more abnormal than hers although he is not a bleeder.

Case 3

This case, like cases 1 and 2, belongs to the hæmophilia-like group. Both the prothrombin consumption and the thromboplastinogen-activity time are distinctly abnormal (table VII). The most striking finding is the very prolonged bleeding-time. Curiously, the results of the various clotting-tests are not constant. The clotting-time is sometimes prolonged but often normal. Sometimes the additions of hæmolysate and of serum cause a fair increase in prothrombin consumption but at other times they have only a slight effect. The thromboplastin-generation test

* A bleeder with a clinical history very similar to that of case 3

is constantly abnormal, and the defect resides in the plasma Occasionally, however, the serum also seems to be defective

The hereditary pattern can be discerned from table vii The thromboplastin-generation test of the parents is at times abnormal Since both the girl and one of her brothers have identical clinical and laboratory findings, it appears quite certain that the disease is hereditary

Discussion

The occurrence of hæmophilia in the female can be accepted because a sufficient number of cases have been published which meet the diagnostic requirements clinical history, specific laboratory findings, and correct hereditary pattern

The cases reported by Israëls et al (1951) and Pola and Svojítka (1957) are typical

The patient of Taylor and Biggs (1957), who comes from a hæmophilic family and has a bleeder brother, has a normal son This makes it improbable that both X chromosomes are defective

Fantl and Margolis (1955) reported a female, with mild hæmophilia, who has a son who bleeds very easily, his blood closely resembling that of hæmophilia

The patient of Choremis et al (1956), a little girl, likewise appears to be a true hæmophiliac Unfortunately, the family history was unobtainable

Some cases—e g , that reported by Beller and Koch (1956)—do not correspond to true hæmophilia clinically mucosal bleeding is rather uncommon in hæmophilia

Hardisty (1957) has reported in a woman a bleeding condition that appears to be Christmas disease

Case 1 is particularly interesting because her blood is indistinguishable from that of true hæmophilia by all known tests It is reasonably certain that the condition is congenital, because she had no serious illness before the discovery of her tendency to bleed If her disease is true hæmophilia, the hæmophilic genes of both X chromosomes must be present Since both her parents are clinically normal, the cause of her condition is best explained by mutation This, to be sure, is speculation, and the proof can only be established by her offspring All her sons should be bleeders and all her daughters carriers, if this assumption is correct

Case 2 particularly illustrates the need for careful laboratory studies to establish a definitive diagnosis Without an accurately performed prothrombin-time test and thromboplastin-generation test one could easily mistake her disease and diagnose it as true hæmophilia especially since her blood does not always effectively correct true hæmophilic blood The prolonged prothrombin-time is not caused by lack of prothrombin or of labile factor A serum factor from normal blood corrects both the prothrombin-consumption defect and the prothrombin time Case 2 corresponds in most respects to that described by Hougie et al (1957) Their patient had a much longer prothrombin time but otherwise closely resembles our case They named the condition the " Stuart clotting defect " The condition resembles that of the patient described by Telfer et al (1956)

Cases 3 and 4 correspond to that first observed by Alexander and Goldstein (1953), Larrieu and Soulier (1953), and Quick and Hussey (1953b). The characteristic findings are the prolonged bleeding-time, the impaired consumption of prothrombin, and the poor generation of thromboplastin, with the defect in the plasma Singer and Ramot (1956) suggest the term " pseudohæmophilia B " for this disease " Pseudohæmophilia A " is the name given to von Willebrand's disease, which is likewise characterised by a prolonged bleeding-time but is transmitted as a dominant Pseudohæmophilia B appears to be inherited as a recessive, only the homozygote being a bleeder

The importance of bleeding in females is emphasised by the increased number of such patients reported recently The desirability of standardisation of the diagnostic tests to differentiate the various hereditary bleeding-diseases in women is obvious because it is a primary requirement for their classification A bleeding disease in a girl is especially serious because little is known about the hæmostatic control of menstrual bleeding Nearly all the cases of women with hæmophilia-like conditions were over twenty years old when they were first studied, suggesting that their bleeding was relatively mild Some of these patients—e g , the one studied by Pola and Svojítka (1957)—have normal menstruation A patient with hyperheparinæmia, whom we (Quick and Hussey 1953c) studied for several years, also has no abnormal menstrual bleeding, although her clotting-time is consistently about an hour The management of a bleeder at the onset of the first menstruation is extremely difficult because so little information has been published and the effect of a coagulation defect on uterine bleeding is unpredictable

Summary

Four girls with congenital bleeding conditions characterised by defective production of thromboplastin are reported

Case 1's disease is indistinguishable from classical hæmophilia, except that the family history is negative

Case 2 has, in addition to defective consumption of prothrombin and defective generation of thromboplastin, a prolonged prothrombin time Her disease is similar or probably identical with the entity recently named " Stuart clotting defect "

Cases 3 and 4 have a normal prothrombin time but a very prolonged bleeding-time, defective consumption of prothrombin, and faulty generation of thromboplastin The suggested name " pseudohæmophilia B " has been tentatively accepted to designate this disease

The differential diagnoses of this group of diseases is discussed, and their clinical and genetic aspects are presented

From the National Institute of Public Health, Utrecht, and the Infectious Diseases Department of the Wilhelmina Hospital, Amsterdam

IT may be regarded as an accepted fact that, when diphtheria is suspected, the patient ought to be injected with antidiphtheritic serum without delay It is indefensible to wait until the result of the bacteriological examination is known The bacteriological diagnosis should only confirm the bedside diagnosis made by the practitioner The desirability of the early injection of antiserum is discussed in more detail by Tasman and Lansberg (1957)

Opinions differ, however, about the best way of injecting antiserum It is generally deemed advisable to inject it intramuscularly and only to resort to intravenous injection in severe cases (Chatterjee 1954, Gorter 1948, Hyman 1948, Cecil and Loeb 1952, Herderschee 1953, Christie 1955) Lepintre (1954) goes so far as to maintain that the antiserum must never be injected intravenously but should always be injected either intramuscularly or subcutaneously

Tasman et al (1954, 1955) have shown that the saliva of diphtheria patients usually contains diphtheria toxin When purified diphtheria antiserum (obtained from horses) is injected intramuscularly, the antitoxin is sooner or later excreted in the saliva via the salivary glands and will then neutralise this toxin Actively immunised persons do not excrete the (homologous) antitoxin in their blood through the salivary glands

We thought it worth while to investigate this excretion of antitoxin through the salivary glands more closely and, more especially, to find if there were any differences in this respect between patients injected intramuscularly and those injected intravenously

Excretion of Antitoxin in Saliva

The saliva of patients was tested for antitoxin at various times after either intramuscular or intravenous injection of purified diphtheria antiserum The results are shown in table I[1]

This excretion of antitoxin in the saliva via the salivary glands is very important Our investigation showed that, after only 30 minutes, the saliva of all but one of the intravenously injected patients already contained antitoxin and had therefore become atoxic[2] In other words, from this moment no more toxin would be absorbed from the saliva flowing over the inflamed and damaged membranes of the tonsils and the pharynx In the intramuscularly injected patients this rapid excretion of antitoxin was exceptional, usually it was a long time before the saliva contained any antitoxin During this interval diphtheria toxin could be absorbed from the saliva through the inflamed membranes of the tonsils and the pharynx

TABLE I—EXCRETION OF ANTITOXIN IN SALIVA

Intramuscular injection (average dose 28,000 A U)		Intravenous injection (average dose 12,000 A U)	
No of cases	Time taken for antitoxin to reach saliva	No of cases	Time taken for antitoxin to reach saliva
1	30 min	12	30 min
3	4–5 hr	1	6 hr
3	10 hr		
9	1–9 days		

This difference between the two groups of patients is the more striking because the intramuscularly injected patients received on the average 2 5 times as much antitoxin as did those injected intravenously

Blood-serum Titres

We took samples of blood from patients before they received the antidiphtheritic serum either intravenously or intramuscularly and at set times after its injection, and determined the antitoxin titres Table II shows the results in a greatly abridged form, the titres are expressed as percentages of the highest titre found

---

[1] For lack of space the numerical results of this investigation are given only in summarised form here We hope to publish the full details elsewhere

[2] The first samples of saliva were taken 30 minutes after the serum had been injected It is by no means inconceivable that antitoxin may appear in the saliva of the intravenously injected patients even before that time

* In these calculations the titres before the injection of antiserum have been subtracted from the titres found after the injection because we are here concerned solely with the course of the antitoxin level resulting from the injection of heterologous diphtheria antitoxin

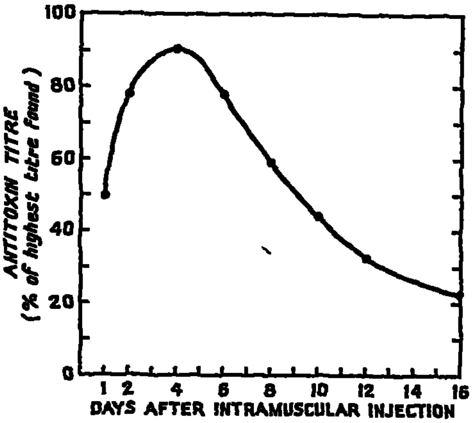

Fig 1—Mean titres of antitoxin in serum after intramuscular injection

The absorption and excretion of antitoxin from antiserum injected either intramuscularly or intravenously varied greatly from one patient to another It is, however, obvious that the antiserum is absorbed much more slowly after intramuscular injection, the highest titre in the serum not being reached until after 2–6 days on the average

The average titres expressed as percentages of the highest titre found are shown after intramuscular injection (fig 1) and after intravenous injection (fig 2)

One is immediately struck by the great similarity between the two curves of antitoxin titres This is brought out even more clearly when the percentage titres (expressed as percentages of the highest titre found) are plotted on a logarithmic scale and in both cases the average titre found 4 days after the injection is taken as 100%[3]

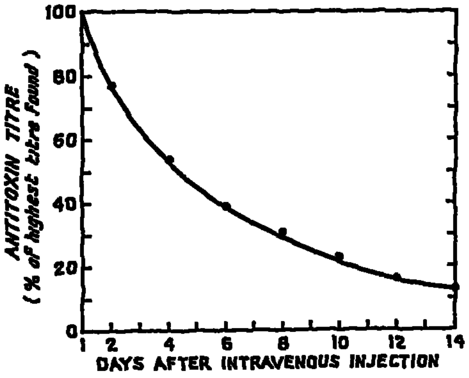

Fig 2—Mean titres of antitoxin in serum after intravenous injection

Fig 3 gives the results of these calculations Here the two lines practically coincide from the fourth day after the injection of the antiserum From this we conclude that the antitoxin in the intravenously injected antiserum is not excreted more rapidly than that in the intramuscularly injected antiserum Hence in this respect there is no reason why the intramuscular injection of antiserum should be preferred to the intravenous Madsen (1936) reached the same conclusion after a similar investigation

In view of these results the obvious thing would have been to test the presumptive superiority of the intravenous method, compared with the intramuscular, on a large number of patients, but such a plan would meet with many difficulties, the chief obstacle being the small number of diphtheria patients available at present For this reason we confined ourselves to experiments with laboratory animals

Design and Application of an "Animal Model"

When a guineapig is injected with a certain number of lethal doses of diphtheria toxin it can be saved from death or protected from typical morbid symptoms by injecting antitoxin before or shortly after the injection of toxin When the quantities of toxin and antitoxin to be injected have been fixed, the interval between the injection of toxin and that of antitoxin will determine the clinical picture If a short interval is chosen, the guineapigs will show only very slight transient symptoms or none at all If a long interval is allowed, most of the guineapigs will show severe manifestations (much loss of weight, severe cardiac manifestations, and paralyses) or most of them will die

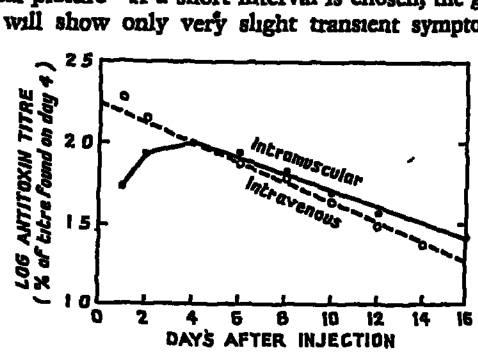

Fig 3—Logarithms of titres of antitoxin in serum after intramuscular and after intravenous injection

In other words, therefore, a suitable choice of the three determining factors—amount of toxin, amount of antitoxin, and length of time between the two injections—will make it possible to control the clinical picture so that special attention can be given to different aspects of it

A well-standardised "animal model" of this kind will also provide an excellent means of ascertaining experimentally the influence of a fourth factor—e g, the route by which the antitoxin is injected

After preliminary experiments we used male[4] guineapigs weighing 300–350 g in all our further investigations These were injected subcutaneously with 5 M L D of diphtheria toxin at the beginning of each experiment A certain number of hours afterwards the guineapigs were injected with 1 antitoxic unit of diphtheria antitoxin, half of them receiving this antitoxin intramuscularly and the

---

[3] On the average the absorption of intramuscularly injected serum is complete at the end of this period The subsequent excretion of this intramuscularly injected antitoxin is strictly comparable to that of the intravenously injected antitoxin

[4] The intravenous injection of antiserum is technically much simpler in the male guineapig than in the female The antiserum was injected into a branch of the femoral vein in the subcutaneous tissue of the inside of the thigh

other half intravenously By determining beforehand the time required for the different injections it was possible to ensure that the time between the injection of the toxin and that of the antitoxin was the same for every guineapig in each experiment. In each experiment some guineapigs were injected with toxin only, without a subsequent injection of antitoxin, as controls These controls were always dead on the 2nd or 3rd day after the injection of the toxin.

Experiment I

Two groups of guineapigs received 5 M.L.D of diphtheria toxin subcutaneously, after 9 hours 1 A.U of antitoxin was injected intramuscularly into 15 guineapigs and intravenously into 15 others Of the intramuscularly injected guineapigs 4 died, after 2, 6, 7, and 9 days, whereas 4 of those injected intravenously died after 6, 7, 8, and 10 days All the guineapigs were weighed twice daily, after which the mean weight of each group was calculated Table III gives the results of this experiment, which are graphically represented in fig 4 The initial weight per group is here taken as 100

From these results we may conclude that the guineapigs injected intramuscularly with antiserum showed a greater and more prolonged loss of weight than did those injected intravenously Therefore the general condition of the former throughout the experiment was considerably worse than that of the latter under otherwise identical conditions

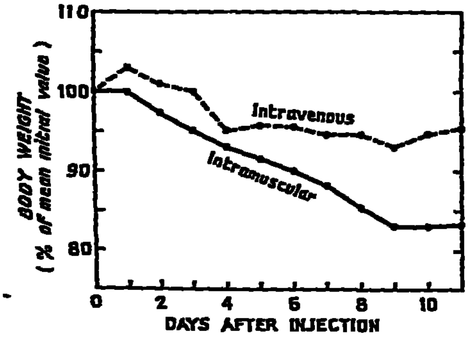

Fig 4—Weights of guineapigs after intramuscular and intravenous injection of antidiphtheritic serum.

Experiment II

If the interval between the injection of toxin and that of antitoxin is long, one may expect a greater number of deaths in both groups of guineapigs To test the difference between the intramuscular and the intravenous injection of antiserum, two groups of 65 guineapigs were subcutaneously injected with 5 M.L.D of diphtheria toxin. After 9½ hours they were given 1 A.U of antitoxin. One group was injected intravenously with the antitoxin and the other intramuscularly The results of this experiment are given in table IV

These figures suggest that guineapigs previously treated with toxin have a considerably better chance of survival when injected intravenously than when injected intramuscularly with the same dose of diphtheria antitoxin.

It may at first sight seem strange that lengthening of the interval between the toxin and antitoxin injections by only 30 min. (from 9 to 9½ hr) should have such a striking effect on the mortality-rate of the guineapigs In experiment I (9 hr interval) only 4 guineapigs died in each of the two groups (about 25%), whereas in experiment II (9½ hr interval) 52% of the guineapigs died in one group and 86% in the other This result is closely related to the experimental conditions If we had chosen different doses of toxin and of antitoxin and a different interval we would have obtained results quantitatively different from these For further general considerations on this "animal model" see below

Experiment III

It was to be expected that the use of a considerably shorter interval between the injection of toxin and that of antitoxin would lead to fewer deaths and provide information about the effect of the method of injection on the paralyses which appear in a later stage of diphtheria

TABLE IV—MORTALITY AMONG GUINEAPIGS INTRAVENOUSLY OR INTRAMUSCULARLY INJECTED WITH DIPHTHERIA ANTITOXIN, DIPHTHERIA TOXIN HAVING BEEN INJECTED 9½ HOURS BEFORE NUMBER OF ANIMALS IN EACH GROUP 65, TOXIN DOSE 5 M.L.D ; ANTITOXIN DOSE 1 A U

10	1	6
11	2	4
12	0	6
13	4	2
14	0	1
15	1	1
Total	34	56

For this purpose two groups of 46 and 48 guineapigs were given 5 M.L.D of antitoxin subcutaneously and 6½ hours later were injected either intravenously or intramuscularly with 1 A.U of antitoxin. Table V shows the incidence of paralysis this primarily and chiefly affected the hind legs Fig 5 shows these results

These data show that, under the conditions of the experiment, paralysis came on fairly late after 16 days among the intramuscularly injected guineapigs, and not until after 21 days among those intravenously injected. 32 days after the beginning of the experiment all the intramuscularly injected guineapigs showed unmistakable signs of paralysis, whereas only 33% of those injected intravenously did so

It thus appears that the intravenous injection of antiserum very considerably reduces the chance of the development of postdiphtheritic paralysis These paralyses also appear later than they do after the intramuscular injection of antiserum.

Experiment IV

It is well known that the heart is the organ that suffers most from the harmful effect of diphtheria toxin. Therefore in our efforts to design a well-planned experiment we paid full attention to the heart.

For this purpose two groups of 184 guineapigs were subcutaneously injected with 5 M.L.D of diphtheria toxin. After

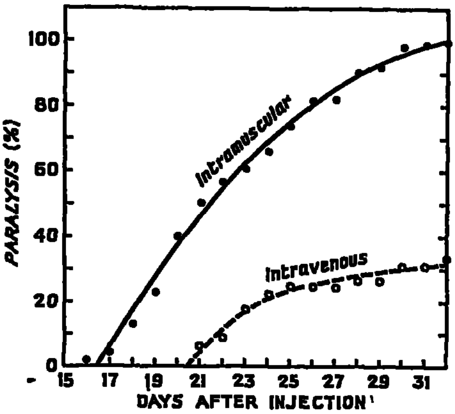

Fig 5—Incidence of paralysis among guineapigs after intramuscular and intravenous injection of antidiphtheritic serum

6$^{1}/_{2}$ hours they all received 1 A U of antitoxin, the first group intravenously and the second intramuscularly After 1, 3, 6, 9, 12, and 15 days about a sixth of the guineapigs in each group were killed, and their hearts were removed and fixed in 20% aqueous solution of formalin The guineapigs which had died spontaneously at the times mentioned were regarded as "killed", and their hearts were treated in the same way Frozen sections were made of roughly the same part of the wall of the left ventricle of each heart For the study of the myocardial lesions these sections were stained with hæmatoxylin-eosin For the demonstration of fatty degeneration separate sections were stained with sudan III

To provide a standard of comparison for the microscopically observed histological changes in the hearts of the treated guineapigs we killed 4 normal non-treated guineapigs per group of killed animals and spontaneous deaths The hearts of these animals were prepared in the same way

This pathological study was organised in such a way that the member of our team who performed the dissections and the microscopic examination (H H V) never knew in advance to which category (injected or non-injected) the various guineapigs belonged Thus an objective appreciation of the material was ensured

As regards myocarditis, the changes observed ranged from very slight local infiltration with mononuclear cells to strong, practically diffuse, infiltration with many mononuclear cells, sometimes accompanied by leucocytes, lymphocytes, or fibroblasts

As regards fatty degeneration of the heart, the mild cases showed only a few fat-globules in a few muscle-fibres In severely degenerated hearts practically all the fibres contained numerous, sometimes fairly large, drops of fat

In this experiment also some control guineapigs were injected with toxin only and not with serum All died within 2 days, their hearts always showing considerable fatty degeneration

The gravity of the lesions microscopically observed in the hearts of the different guineapigs varied greatly and was (more or less quantitatively) classified as ±, +, ++ or +++

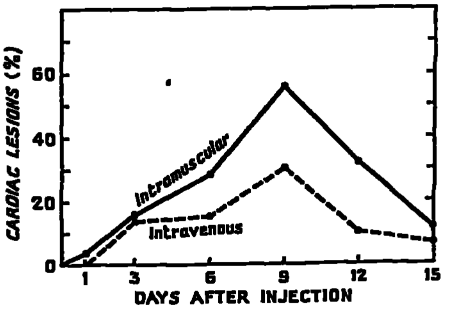

Fig 6—Incidence of cardiac lesions among guineapigs after intramuscular and intravenous injection of antidiphtheritic serum

Occasionally the non-injected controls (neither toxin nor antiserum) also showed slight lesions of the myocardium, classifiable as ± or + This was the case in 15 of the 24 normal non-treated controls Fatty degeneration of the heart was not found in any of the non-treated controls

Some of the treated guineapigs also showed such slight lesions It seemed only logical to leave these slight lesions, also found in non-treated controls, out of account Consequently table VI includes only the grave lesions (myocarditis and fatty degeneration taken together) The data are also shown in fig 6

More or less severe lesions of the heart (myocarditis and fatty degeneration) were found in both groups This is understandable because all the guineapigs had been exposed to the injurious action of 5 M L D of diphtheria toxin for 6$^{1}/_{2}$ hours before they were injected with antitoxin

Under the conditions of the experiment these lesions reached their climax after 9 days, recovery then setting in at the same time in both groups Of course this last circumstance may have been due to chance It is not impossible that, if the experiment were arranged differently, the times of recovery would not coincide

Finally we tried to divide the observed lesions into myocarditis and fatty degeneration

The numerical data and graphs relating to this part of the investigation are not shown here, owing to shortage of space It will suffice to state that the guineapigs injected intramuscularly with antidiphtheritic serum showed more cases of myocarditis and fatty degeneration of the heart than did the intravenously injected ones

TABLE VI—DISTRIBUTION OF SERIOUS LESIONS OF THE HEART FOUND AMONG THE VARIOUS GROUPS OF GUINEAPIGS GIVEN 5 M L D OF TOXIN SUBCUTANEOUSLY, FOLLOWED BY INJECTION OF 1 A U OF ANTITOXIN INTRAMUSCULARLY OR INTRAVENOUSLY AFTER 6$^{1}/_{2}$ HOURS

No of days between serum injection and killing	Intravenously injected		Intramuscularly injected	
	No killed	No of heart lesions	No killed	No of heart lesions
1	30	0	30	1 *(3 3%)*
3	35	5 *(14 3%)*	38	6 *(15 8%)*
6	32	5 *(15 6%)*	31	9 *(29 0%)*
9	29	9 *(31 0%)*	30	17 *(56 6%)*
12	29	3 *(10 3%)*	30	10 *(33 3%)*
15	29	2 *(7 0%)*	25	3 *(12 0%)*

As regards the observed lesions of the heart, there again emerges a clear difference between the results of the two methods, which is strongly in favour of the intravenous injection of antiserum This is easily explained After the injection of intravenous antitoxin the serum of the guineapig is practically immediately "up to titre"—i e, the total amount of antitoxin is available immediately for neutralisation of the toxin still circulating freely at that moment This toxin can then no longer cause a lesion of the heart Possibly part of the toxin which has already penetrated into the myocardium is also neutralised

The effect of the intramuscular injection of antiserum is the same, but slower, because of the comparatively slow absorption of the antitoxin thus injected The toxin still circulating freely is rendered inactive more slowly or can act longer on the myocardium, with all the consequences of this

The difference between the antitoxin titres in the guineapigs injected intravenously and intramuscularly with antiserum will, of course, be greatest in the first few hours This is undoubtedly responsible for the large difference in the incidence of cardiac damage

Summary of Results of Experiments

Groups of guineapigs were subcutaneously injected, 2 at a time, with a constant dose of diphtheria toxin (5 M L D) After a certain number of hours they all received a constant dose of antitoxin (1 A U), half of them being injected intravenously and the other half intramuscularly The intravenous injection of antiserum had a considerably greater therapeutic effect than had the intramuscular The guineapigs injected intravenously with serum showed less loss of weight and more rapid recovery of weight, fewer deaths, less frequent and later development of paralysis, and fewer lesions of the heart (myocarditis and fatty degeneration) than did guineapigs injected intramuscularly

Discussion

The experiments were made under strictly standardised conditions The doses of toxin and of antitoxin injected were the same for all the guineapigs, which were all of the same sex and had the same weight in each pair The time between the injection of toxin and that of antitoxin was the same for each pair In this way we found a quantitative difference between the therapeutic effects of the intravenous and the intramuscular injection of antiserum Had the criteria of these experiments (amount of toxin, amount of antitoxin, and interval between the two injections) been different, we would no doubt have seen the same qualitative differences, but the absolute figures would not have been the same

Obviously the quantitative results obtained with this "animal model" cannot be quantitatively transferred to the therapy of human diphtheria patients The criteria for the latter are different from those applied in the experiment on guineapigs

If, however, the pathogenesis of human diphtheria is determined by the formation of toxin by the diphtheria bacillus infecting the patient and by the effects of this toxin, especially on the heart and the nervous system, we may indeed apply the qualitative results of these laboratory experiments to man

Summarising the results of experiments I–III we may conclude that, for the treatment of human diphtheria also, the intravenous injection of diphtheria antiserum is much to be preferred to the intramuscular route for the following reasons:

(1) After the intravenous injection of antiserum the patient's serum is almost immediately "up to titre"—in other words, the total amount of diphtheria antitoxin is transported very quickly through the blood to the organs concerned Intramuscularly injected antiserum is absorbed only slowly, on the average this absorption is not completed until after 4 days, but it may take as much as 6 days The serum titres of the patients were determined 24 hours at the earliest after the injection of antitoxin, hence we cannot give any figures for the serum-antitoxin levels within a shorter time after the intramuscular or the intravenous injection It can, however, safely be assumed that the relative and absolute differences will be large in the first few hours after the injection

(2) As a non-specific protein, the intravenously injected antitoxin is not more quickly broken down and excreted than intramuscularly injected antitoxin

(3) Very shortly after the intravenous injection of antiserum some of the antitoxin is excreted into the saliva through the salivary glands From this moment the saliva is atoxic, henceforth no toxin can be absorbed from this saliva through the inflamed and damaged tonsils and wall of the pharynx After the *intramuscular* injection of antiserum it usually takes many hours, sometimes even days, for this excretion of antitoxin through the salivary glands to get going During this interval the saliva contains toxin which can be absorbed through the inflamed tonsils and wall of the pharynx.

(4) Lesions of the heart (myocarditis and fatty degeneration) will very probably be less common among intravenously injected than among intramuscularly injected patients These lesions will presumably also be less serious among the former than among the latter

(5) As a group, intravenously injected patients will very probably show fewer cases of paralysis than will intramuscularly injected patients

(6) Under comparable conditions the mortality among intravenously injected patients is likely to be lower than among intramuscularly injected patients

There is no danger attached to the intravenous injection of the antiserum, provided that certain precautions are taken The skin test for hypersensitivity to the antiserum is especially important and should not be omitted

For this test 0 2 ml of the antiserum, diluted to a tenth with saline solution, should be injected intracutaneously on the flexor aspect of the forearm It is absolutely imperative that a weal should form during this injection, if it does not, the intracutaneous injection must be considered unsuccessful and will have to be repeated

If no redness or swelling shows within an hour after the intracutaneous injection, the intravenous injection can safely be given Our experience with many hundreds of patients is that there are then never any serious reactions Some hours after the intravenous injection of serum (enzymatically purified and radically despeciated horse-serum) a few of the patients had slight pyrexia, sometimes accompanied by a rigor This type of reaction proved harmless

If, however, the skin reaction is positive (redness and/or swelling), the serum must be injected intramuscularly and in very small portions at intervals of half an hour or an hour, under the supervision of an experienced person who, if necessary, can administer adrenaline (0 1–1 0 ml of adrenaline hydrochloride 1 1000, according to the patient's age) if the patient shows obvious allergic phenomena

Parish et al (1957) propose a hypersensitivity test in which 0 2 ml of undiluted serum is injected subcutaneously If there is no general reaction within 30 minutes, the whole dose of serum can be injected either subcutaneously or intramuscularly without special precautions This refers to the injection of a prophylactic dose of antitetanus serum (generally 1500 A U in 1 ml)

We do not recommend this procedure for diphtheria patients We believe that the risk of serious allergic reactions is much greater after the subcutaneous injection of 0 2 ml. of undiluted antidiphtheritic serum (4000 A U per ml , the protein content generally being greater than that of prophylactic antitetanic serum) than after the test injection described by us

The doses of antidiphtheritic serum which we have given in the last few years have been 10,000–20,000 A U per patient according to age The results of the determination of antitoxin titres after the intravenous injection have convinced us that an additional intramuscular injection of antidiphtheritic serum would be superfluous

Provided that the precautions described above are observed, there is not the slightest objection to the intravenous injection of antiserum in all cases where an injection may be required Consequently all these patients should be injected not intramuscularly but intravenously with diphtheria antitoxin The intravenous injection of antiserum in patients suspected of diphtheria ought therefore to become the rule and should not be reserved for "serious" or toxic cases, as is still usually done at present

Moreover it is by no means always possible to predict with certainty the course of the diphtheria During an epidemic there have repeatedly been cases which initially seemed mild but became toxic within a few hours and rapidly fatal Some of these patients would probably have been saved if they had been given an intravenous injection of antidiphtheritic serum at the earliest opportunity

It should be borne in mind that, in cases of suspected diphtheria, the first object of the antiserum therapy is the quickest and completest possible elimination of any further absorption of diphtheria toxin (e g, from the saliva) and the binding of the toxin still circulating The investigations here described will have shown that not only the promptness of the injection but also its route can have a decisive effect Not until this has been done will the treatment be directed to combating the damage already done to the heart, kidneys, and nervous system

Summary

An investigation is described which clearly brought out the advantages of the intravenous injection of antitoxic serum in patients suspected of diphtheria, compared with the intramuscular injection still commonly used

The intravenously injected antitoxin immediately brings the patient's serum "up to titre", whereas absorption of the intramuscularly injected antitoxin is slow, usually not being complete until after about 4 days, and sometimes 6 days

Intravenously injected antitoxin is not excreted more rapidly than intramuscularly injected antitoxin

Very shortly after the intravenous injection of antitoxin a small portion of it is excreted through the salivary glands into the saliva, which it renders atoxic Consequently from this moment no more toxin will be absorbed from the saliva through the inflamed and damaged tonsils and wall of the pharynx

The results of experiments on guineapigs indicate that patients intravenously injected with antidiphtheritic serum may be expected to show fewer lesions of the heart (myocarditis and fatty degeneration), fewer post-diphtheritic paralyses, and a lower mortality than patients intramuscularly injected with antiserum

With due observance of the necessary precautions—e g, a skin test for hypersensitivity (which must be negative)—diphtheria antitoxin should be injected not intramuscularly but intravenously whenever such an injection is required, even in mild cases of diphtheria

We are greatly indebted to our colleagues Dr W Smit, Dr J Roos, Dr G L Wilkens, Dr H M van Vessem, Dr A van Dongen, and Dr A M van Rooyen for submitting samples of the saliva and blood from their patients Without their cooperation a considerable part of this investigation could not have been undertaken

HONORARY DEPUTY DIRECTOR, OBSTETRIC MEDICINE RESEARCH UNIT (MEDICAL RESEARCH COUNCIL), UNIVERSITY OF ABERDEEN

The cause of most fœtal malformations is obscure Some types, both animal and human, are inherited and appear in accordance with the mendelian laws The environment of the early embryo may be responsible for other types or may bring out latent tendencies, this has been proved experimentally in primitive animals and some mammals through changes of temperature and pH, mechanical injury, anoxia, dietetic deficiencies, and exposure to X-rays and chemical substances

It is not known whether these factors cause malformations in man, but indirect evidence suggests that fœtal defects may sometimes be brought about by noxious agents or by an inadequate intrauterine environment Abnormal implantation of the ovum, as in tubal pregnancy, is associated with a high incidence of malformations (Mall 1908) The incidence is increased if bleeding has occurred in the early months of pregnancy (Burge 1951, Turnbull and Walker 1956) and in diabetic pregnancies (Peel and Oakley 1949) Gregg's (1941) observation is now generally accepted, that infection with rubella in early pregnancy is often followed by the birth of a deformed child

The incidence of congenital malformations is difficult to estimate The best study based on a defined population is that of Record and McKeown (1949) dealing with Birmingham Several reports based on hospital records are available, but, though the data are no doubt accurate, hospital patients are not necessarily representative of the population from which they are drawn National statistics refer only to deaths certified as due to deformity, and are by no means comprehensive Scottish vital statistics give much information about malformed stillbirths but very little about neonatal or infant deaths Those for England and Wales give no information about the causes of stillbirths and little about infant deaths due to malformations

This study deals with stillbirths and infant deaths associated with malformations The main group used for analysis consists of 37,585 single births to booked patients delivered in the Aberdeen Maternity Hospital in 1938–55 Lest the trends found were produced by selection of patients for hospital confinement, these were compared with those in all Aberdeen births in 1949–55 (Records for 1938–48 were not available on a city-wide basis) These local statistics are compared with certain national data derived from the annual reports of the Registrar-General for Scotland

Method

Group 1—The records of the Aberdeen Maternity Hospital for 1938–55 were searched for fœtal deformity in booked cases The present analysis has been restricted to cases of stillbirth or of infant death The records of infant deaths taking place some time after mother and child were discharged from hos-

TABLE I—DISTRIBUTION OF STILLBIRTHS AND INFANT DEATHS ASSOCIATED WITH CONGENITAL MALFORMATION, ACCORDING TO MATERNAL AGE AND PARITY

Expected numbers in parentheses, discrepancies in cross-totals are due to "rounding-off"
(Aberdeen Maternity Hospital booked cases, excluding twins and abortions, 1938–55)

Age (yr)	Anencephalus					Other malformations of C.N.S.					Other malformations

–19	9 (3 8)	(0 5)	(0 0)	(0 0)	9 (4 4)	12 (5 6)	1 (0 7)	(0 1)	(0 0)	13 (6·4)	3 (5 7)	1 (0 9)	(0 1)	(0·0)	4 (6 5)
20–24	22 (13·0)	6 (6·0)	1 (1 8)	(0 8)	29 (21 5)	26 (19 1)	9 (8 8)	4 (2 7)	(0 9)	39 (31 5)	20 (19 3)	9 (8 9)	6 (2 7)	2 (0 9)	37 (31 8)
25–29	6 (6 5)	6 (6 3)	1 (3 2)	2 (2 2)	15 (18 1)	8 (9 5)	6 (9 2)	2 (4 7)	3 (3 2)	19 (25 6)	14 (9 6)	5 (9 3)	4 (4 8)	3 (3 2)	26 (26 9)
30–34	1 (2 1)	1 (3 1)	1 (2 2)	1 (2 5)	4 (10 0)	3 (3 1)	1 (4 6)	4 (3 3)	3 (3 6)	11 (14 7)	(3 2)	1 (4 7)	2 (3 3)	2 (3 7)	5 (14 9)
35 or more	(0 9)	(1 3)	(1 2)	3 (2 6)	3 (6 0)	2 (1·4)	(1 9)	1 (1 7)	3 (3 8)	6 (8 9)	2 (1 4)	4 (1 9)	4 (1 8)	7 (3 8)	17 (9 0)
Total	38 (26·4)	13 (17 2)	3 (8 5)	6 (7 8)	60 (60 0)	51 (38 7)	17 (25 3)	11 (12 5)	9 (11 5)	88 (88 0)	39 (39 2)	20 (25 6)	16 (12 6)	14 (11 6)	89 (89 0)

pital are unavoidably incomplete, especially through emigration from the city, but this fact is unlikely to have introduced bias of any importance The data were analysed by age and parity

Group 2—Since 1949 punch-card records of all births in the city of Aberdeen have been maintained in the university department of midwifery, and those for 1949–55 have been used in this investigation to provide data referring to a defined population In addition to an analysis by age and parity the data were examined for primiparæ by social class and height

In groups 1 and 2 plural pregnancies were excluded to simplify analysis In group 2 the analysis was further restricted to legitimate births to patients resident in the city

Group 3—The annual reports of the Registrar General for Scotland (1939–55) provided data for stillbirths attributed to fœtal malformation, broken down by social class and by region Data by age and by parity (but not both together) are also available

Results

Incidence

Among the 37,585 single births in group 1 were 237 stillbirths and infant deaths attributable to congenital malformation (6 3 per 1000 births) These included 60 due to anencephalus (1 6 per 1000 births), 88 due to other deformities of the central nervous system (2 3 per 1000 births), and 89 to other malformations (2 4 per 1000 births), the equivalent rates on the basis of 20,961 city births (group 2) were 1 5, 1 8, and 2 2 respectively

It has been indicated above that these rates may be a little low owing to failure to identify all the infant deaths Fully comparable data are not easily extracted from national statistics In Scotland in 1939–55 the incidence of stillbirth certified as due to anencephalus was 2 7 per 1000, that of stillbirths plus first-year deaths due to malformations of the central nervous system was 3 7 per 1000, and those due to other types of malformations 3 9 per 1000 * These national rates are higher than those found for Aberdeen It will be shown below that the stillbirth-rates due to anencephalus in the city of Aberdeen are lower than those in the other large Scottish cities

Maternal Age and Parity

Table I gives the distribution by age and parity, in the Aberdeen Maternity Hospital group, of stillbirths and infant deaths due to the three groups of deformities distinguished above Closely comparable results were obtained in the smaller Aberdeen city group Since the numbers in several cells are very small, the calculation of rates is unprofitable, and instead the "expected numbers" in each age and parity group are shown, these have been calculated on the assumption that the cases of deformity were distributed in strict proportion to the total number of patients in each cell

Among the younger primiparæ the number of stillbirths and infant deaths due to anencephalus and other malformations of the central nervous system is more than twice the expected number No other notable excesses or deficits are evident On the other hand, in the group of "other malformations" the only clear excess is among mothers aged 35 or more The data show that much of the excess in the oldest age-group is attributable to mongolism (The deficit in the age-group 30–34 is believed to be due to chance)

Comparable national figures are unavailable The Registrar-General gives stillbirth-rates by age and by order of birth separately but does not give similar information for infant deaths The stillbirth-rates by age show relatively high incidences for anencephalus before the age of 20 and after that of 35, those for other malformations of the central nervous system and for "other malformations" are high only at the older ages Stillbirth-rates by birth order indicate an erratic increase with parity for anencephalus and other malformations of the central nervous system, there is no very definite trend by parity in the group "other malformations"

TABLE II—DISTRIBUTION OF STILLBIRTHS AND INFANT DEATHS DUE TO CONGENITAL MALFORMATION, BY MATERNAL HEIGHT AND SOCIAL CLASS

Expected numbers in parentheses, discrepancies in cross-totals are due to "rounding-off"
(City of Aberdeen, legitimate first single births 1949–55)

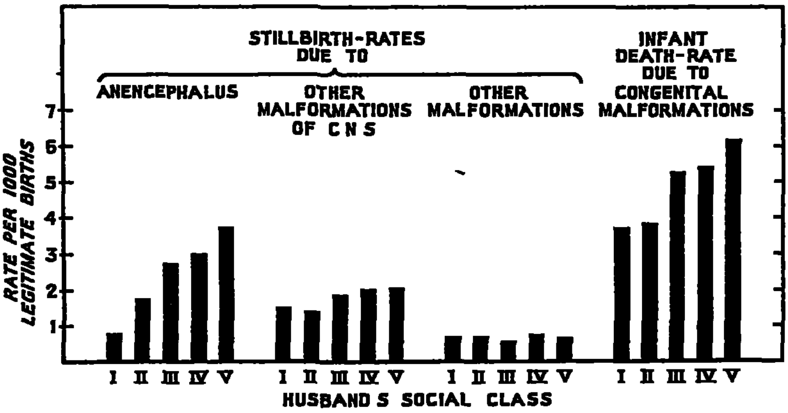
Less than 5 ft 1 in.	2 (0 2)	(2 3)	5 (1 2)	7 (3 8)	1 (0 3)	2 (2 6)	4 (1 3)	7 (4 2)	(0·3)	4 (2 5)	1 (1 3)	5 (4·0)
Total	2 (2·4)	5 (10·4)	10 (4 2)	17 (17·0)	1 (2 7)	12 (11 6)	6 (4 7)	19 (19 0)	1 (2·6)	13 (11 0)	4 (4 5)	18 (18·0)

---

* The national rate for anencephalus is presumably reasonably accurate, since the condition is easy to diagnose and virtually all anencephalic babies are stillborn The rate cited here for other malformations of the central nervous system comprises stillbirths and infant deaths certified as due to hydrocephalus spina bifida, and ' other malformations of the central nervous system ' The group of ' other malformations ' (here assumed to exclude abnormalities of the central nervous system) includes deaths due to unspecified abnormalities, and ' monsters '



Incidence of stillbirths and infant deaths due to congenital malformations, according to social class (legitimate births, Scotland 1950-55)

Social Class and Height

In the data for 8245 married primiparæ resident and delivered in the city of Aberdeen in 1949–55 the social class and height were both specified in 8221 records Table II gives the distribution of stillbirths and infant deaths in the three ætiological groups previously distinguished, together with the numbers expected Although the numbers are small, there is clearly an excess of anencephalus and, to a lesser extent, of malformations of the central nervous system in the lower social classes and in small women These trends do not appear in the group " other malformations "

The Registrar General for Scotland has, since 1950, published data relating to legitimate stillbirths due to congenital deformities Fig 1 shows that, as social status falls, there is a steady increase in the incidence of anencephalic stillbirths There is a smaller, but similar, social-class trend in stillbirth-rates due to other malformations of the central nervous system but none in stillbirths from " other malformations " Infant deaths due to " congenital malformation " also show an increase in rate as social class falls, but unfortunately these deaths cannot be subdivided into specific ætiological groups

Geographical Differences

In 1950-55 there were 2919 stillbirths certified as due to congenital malformations among 563,863 births in Scotland—a rate of 5 17 per 1000 births The distribution of these according to place of birth showed that the highest incidence was in central and southern Scotland, followed by the north-eastern counties, with the lowest incidence in the crofting counties in the north and west. These differences were due largely to variations in the incidence of anencephalic stillbirths, the incidence of which was as follows

Crofting counties of North and West Scotland (Orkney, Shetland, Caithness, Sutherland, Ross and Cromarty, Inverness, Argyll, Bute)	1 29 per 1000 births
Mainly agricultural counties, central and north-east (Perth, Nairn, Moray, Banff, Aberdeen, Kincardine, Angus)	2 15 per 1000 births
Agricultural counties of south, with scattered industrial areas (Ayr, Wigton, Kirkcudbright Dumfries, Peebles Selkirk, Roxburgh, Berwick)	2 65 per 1000 births
Central counties, mainly industrial (Dunbarton, Clackmannan, Kinross, Fife, Lanark, Renfrew, Mid-, West, and East Lothian, Stirling)	2 95 per 1000 births

The incidence per 1000 births of anencephalic stillbirths in the four large cities of Scotland was Aberdeen, 1 7, Edinburgh, 2 5, Dundee, 2 9, Glasgow, 3 1 The order is that which might be expected from a knowledge of the social history of each city, on the assumption that poor social conditions predispose to anencephalus

Conclusions

The literature on the effects of age, parity, social class, and other factors on the incidence of fœtal malformations of various kinds is fairly extensive, but there is much disagreement, and few trends seem to have achieved general acceptance The facts given here suggest that primigravidæ living in poor social circumstances, particularly in industrial communities, have a higher risk than any other group of pregnant women of fœtal death due to malformation of the central nervous system

These facts are as follows

(1) The geographical distribution in Scotland of stillbirths due to malformations of the central nervous system, especially anencephalus, shows the highest rates in the central industrial belt, and the lowest rates in the crofting counties of the west These differences are unlikely to be due to differences of certification, and do not obtain in stillbirth-rates due to malformations other than those of the central nervous system

(2) National statistics—available for women of all parities—show a distinct social-class gradient in stillbirths due to anencephalus, there is a *less steep gradient in stillbirths due* to other malformations of the central nervous system, and none in those due to " other malformations "

(3) Aberdeen data point to a relatively high incidence of anencephalus and other malformations of the central nervous system in young primigravidæ, especially those aged less than 20 *Very few of such young primigravidæ* come from the upper social classes

(4) Closer examination of the Aberdeen cases, which are too few to admit of definite conclusions being drawn, indicates that, within social classes IV and V, it is those undersized women, stunted by the environment in which they have grown, who have the highest incidence of stillbirth and infant death due to malformation of the central nervous system

It is unprofitable, on present evidence, to speculate too far on the nature of possible environmental causes of congenital malformations, especially of the central nervous system Several factors might act together or separately, and different factors may produce the same end-results by interfering with one specific phase of organogenesis Nor should it be inferred from our data that environmental influences are necessarily major " causes " of malformations of the central nervous system, at most, such influences probably act by bringing out latent tendencies The genetics of anencephalus have been discussed comprehensively by Penrose (1957)

One final point may be made the hypothetical environmental influences need not necessarily be present for the first time during early pregnancy For example, if a poor diet is regarded as a possible predisposing factor, chronic malnutrition during growth and adolescence may be as significant as an inadequate diet during early pregnancy Prevention is likely to depend on long-term general measures which will secure high standards of growth and health Measures aimed specifically at improving the diet and health of mothers during the first four weeks of pregnancy, by the end of which time the neural canal of the embryo has closed, are obviously impracticable

LEIOMYOMA OF STOMACH

J H HIGHMAN
M B Lond
MEDICAL REGISTRAR, ROYAL MASONIC HOSPITAL, LONDON, W 6

THE estimated incidence of gastric leiomyoma varies greatly Meissner (1944) found twenty-three affected stomachs (eleven with multiple tumours) in fifty random necropsies, and Riemets (1930) thirty-two affected stomachs in two hundred consecutive necropsies Many of these tumours were but a few millimetres in diameter Clinically significant tumours are much less common Marshall (1955) states that 4 8% of gastric tumours are benign, while Minnes and Geschickter (1936) estimated that leiomyomata form 36% of benign gastric tumours and are the commonest type of benign new growth of the stomach Thus it would seem that leiomyomata may account for about 2% of all gastric tumours This agrees with Cowdell's (1950) estimate of 2 4% but is much higher than the estimate of 1 in 2000 given by Ingram and Johnson (1956), whose figure probably more closely corresponds to common experience

The present case is reported because of the long period of preoperative observation, the confusion of the gastric mass with the spleen, and the success of surgery in a patient aged 84

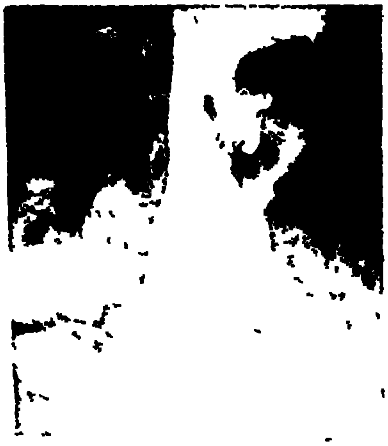

Fig 1—Large ulcerated filling defect arising from the greater curvature

Case-report

A woman, aged 78, was first seen in October, 1950, with a history of having vomited much blood ten days earlier, followed by the passage of black tarry stools For the previous few months she had felt vaguely unwell with upper abdominal discomfort, which was slightly relieved by alkalis She stated that three and a quarter years before this admission she had begun to feel tired and faint and was treated by her doctor for anæmia On admission she was alert but very pale The only significant finding was a mass situated in her left hypochondrium, measuring about 5 in. by 3 in, and resembling an enlarged spleen Her hæmoglobin was 40% She was treated by blood-transfusion and with ferrous sulphate by mouth, and on discharge her hæmoglobin was 88% Biopsy of her sternal marrow showed that it was hyperplastic, with active erythropoiesis of normochromic type Liver-function tests, bleeding-time, and clotting-time were normal A barium meal showed no gastric or œsophageal varices but showed mild pseudo-hypertrophic gastritis No gastric ulcer or neoplasm was seen, and the duodenal cap appeared normal

The patient remained well for a year and then had a slight melæna Two years after this (in October, 1953) she was readmitted with increasing listlessness, tiredness, and further melæna On examination the same mass was felt and the hæmoglobin was 42% Again the patient was transfused and given oral iron, her hæmoglobin being brought up to 83% before discharge Thereafter she remained very well until August, 1957, when she was readmitted complaining of two days' faintness and passing tarry stools She had had a small hæmatemesis three months before

On admission the only significant finding was the mass situated below her left costal margin and extending almost to her umbilicus There was no clinical evidence of portal hypertension or of hepatic failure Her hæmoglobin was 38%, and a blood-transfusion was given, eight pints being required to increase her hæmoglobin to 81%

Further treatment and progress—When the patient's condition had sufficiently improved, liver-function tests were done and showed serum-bilirubin, direct 0 1 mg per 100 ml, indirect 0 4 mg per 100 ml, total 0 5 mg per 100 ml, serum-alkaline phosphatase 6 King-Armstrong units, thymol turbidity 1 unit, thymol flocculation 0 unit, serum-colloidal gold 0 unit, zinc-sulphate turbidity 4 units, ammonium-sulphate turbidity 1 unit The episodes of bleeding were thought to be due to œsophageal varices in association with portal hypertension, the mass in the left hypochondrium being regarded as splenic A barium swallow and meal showed that the œsophagus was normal However, a large ulcerated filling defect arising from the greater curvature of the stomach was seen (fig 1)

Laparotomy (Mr Harold Edwards) revealed a hard irregular growth on the anterior wall of the stomach There were enlarged lymph-nodes in the omentum, but the liver contained no metastases A second pale yellow subserous tumour, 2 cm in diameter, was seen on the anterior wall of the stomach 5 cm above the larger mass A sleeve resection of the stomach was done, the mass being removed entire Postoperative progress was satisfactory, and on discharge the patient's hæmoglobin was 96%

Pathological report (Dr J H O Earle)—The operation specimen was part of the stomach wall and measured 13 cm × 8 cm, with a central protuberant area 5 5 cm in diameter with central ulceration (fig 2) This was continuous with the tumour (10 5 cm × 12 cm × 8 cm) outside the stomach wall On section the tumour was seen infiltrating between the mucosa and the serosa Centrally it infiltrated directly through the serosa to spread as a large extragastric mass The tumour appeared grey-white flecked with yellowish areas of necrosis and areas of hæmorrhage Microscopy showed a leiomyoma with areas of degeneration and hæmorrhage No invasion of lymph-nodes was found The relative absence of mitoses and the mature type of muscle-cell indicated that the tumour was benign

cine, valine, and leucine

Discussion

Leiomyomata usually give rise to symptoms in the older age-groups, 75% in the fifth to seventh decades (Baker and Good 1955) In fifty-one cases reported with clinical details (Christensen 1957, Cowdell 1950, Davis and Adams 1956, Down 1930, Golden and Stout 1941, Harris 1957, Lund 1955, Marshall and Cherry 1955, Morrin 1956) bleeding was the commonest presentation (74%) and was more often severe and acute than occult Abdominal pain occurred in 69%, and a mass was felt in 40%, in one case the mass was confused with the spleen Other clinical manifestations include pyloric obstruction, volvulus of the stomach (Ker 1955), and perforation and bleeding into the peritoneum (Cowdell 1950, Millar 1928) Most cases present after a very short history, but where pain predominates the history may be long, in one there was a seven-year history and a barium meal showed displacement of the stomach six years before operation (Ker 1955) Another patient gave a fifteen-year history (Davis and Adams 1956) In no case has a recurrence been reported, even in cases followed for thirteen years (Morton, et al 1956) and seventeen years (Harris 1957)

This description underlines the essentially benign nature of most of these tumours Malignant deterioration is said to occur, but even histologically malignancy is difficult to determine (Golden and Stout 1941) and is best assessed by the frequency of mitotic figures (Lumb 1951) Death from hæmorrhage is a greater danger than malignancy, so resection is strongly indicated The frequency of massive hæmorrhage and the absence of cachexia in the presence of an abdominal mass distinguish leiomyoma from carcinoma of the stomach

Radiological abnormalities occur in the large majority of gastric leiomyomata (Baker and Good 1955), and the benign nature of the growth may be suggested by the radiological picture A subserous tumour may be visible as a soft-tissue shadow on straight radiography (Davis and Adams 1956) and may displace surrounding viscera, it may distort the barium-filled stomach by traction, or by pressure appear as an extrinsic mass distorting the mucosal folds (Baker and Good 1956)

A submucous tumour may produce a punched-out filling defect of the barium-filled stomach, usually arising from the gastric wall and leaving the curvatures regular The rugæ are obliterated in the immediate region of the tumour but around it appear normal in distribution and arrangement The tumour does not disturb peristalsis or cause spasm (Moore 1924) When ulceration takes place, the mucosal folds do not converge on the crater (Abrams 1954)

Summary

A gastric leiomyoma was present for ten years before operation at the age of 84

The principal features were repeated hæmorrhage and a palpable mass closely resembling an enlarged spleen

A normal barium meal initially led to the diagnosis of splenic anæmia and œsophageal varices

Seven years later the barium meal was grossly abnormal

Successful removal [illegible] tumour led to complete recovery

I wish to thank Dr T C whose care this patient was ad for his help an for the and gastrecto

ACCIDENTAL POISONING IN CHILDHOOD

AN EXPERIMENTAL APPROACH TO THE PREVENTION OF POISONING BY TABLETS

Hugh Jolly
M D Cantab, M R C P, D C H
CONSULTANT PAEDIATRICIAN, PLYMOUTH CLINICAL AREA

T R W Forrest
M R C S
SCHOOL MEDICAL OFFICER, PLYMOUTH

Young children are often poisoned through swallowing drugs in tablet form which have been prescribed for adults, and it has been felt that the attractive appearance of these tablets is one factor in the problem An experiment was therefore carried out to determine the frequency with which different colours were chosen by children when offered a selection of ten coloured tablets By this means it was hoped to determine which colours were least popular among children and might therefore be most suitable for adult tablets

Method

The children tested ranged in age from 1 to 8 years Below the age of 1 the child tended to take more than one tablet, and his grasp was insufficiently accurate to allow of an assessment as to which was his primary choice The same was true of some of those over 1 year of age, in which case the child was not included in the study Those over 8 years were not included, since they were regarded as being beyond the age at risk The children tested were inpatients, outpatients, and those attending for school medical examinations Each child was offered a plate on which were ten lactose tablets coated in the following colours blue, black, brown, orange, white, yellow, pink, green, wine, and magenta For each child the plate was shaken and turned round to reduce any error from the child choosing the nearest tablet Similarly, to obviate any personal bias in the adult making the test, a number of different testers were employed

No attempt was made to introduce the question of different tastes into the test It has been suggested that bitter tablets would be less often accidentally swallowed by children, but many of the poisons taken in this way do taste unpleasant, so it seems that the child can swallow a handful before he appreciates the unpleasant taste

Results

613 children were tested, of whom 316 were boys and 297 girls Age did not appear to be significant in relation to the colour chosen but the ages of the children were

Age (yr)	*No of children tested*	*Age (yr)*	*No of children tested*

The results, in order of preference, were

NO OF TABLETS SELECTED

Colour	Boys	Girls	Total
Magenta	52	52	104
Pink	39	35	74
Blue	25	41	66
Orange	33	31	64
Brown	36	25	61
Yellow	30	26	56
White	30	22	52
Green	21	26	47
Black	25	20	45
Wine	25	19	44

Discussion

These results show the bright colours to be the most popular, with magenta an easy winner Brown, a dull colour, is relatively high on the list, presumably because of its similarity to chocolate Wine and black are understandably found at the lower end of the list, though green's low placing was surprising

The results suggest the use of black tablets, but these have the disadvantage that, if spilt on the floor, they would not so easily be seen and might later be picked up by children It is significant that white, though a bright colour, was not in the popular range, and we think this may be because the children believed that the white one was a "pill" and not a sweet In view of these results, and particularly if this argument is valid, it would seem wiser for tablets to be kept white in order that they should look like "pills", rather than that attractive colours should be introduced which make them look like sweets To achieve this it is not only a matter of persuading the chemist to manufacture white tablets, but of educating doctors and patients to accept only such tablets Robinson (1956) pointed out that his firm (Evans Medical Supplies) had produced a white form of tab ferr sulph, but that these were not wanted and that the demand was for coloured tablets

Against the use of white tablets it might be argued that aspirins are of this colour and yet often poison children It is felt, however, that this is because aspirins are the commonest household tablet

Finally it must be emphasised that the choice of a suitable colour is only one of the means of lowering the rate of accidental poisoning by tablets Ideally (Jolly 1956) all poisonous tablets should be dispensed in 'Cellophane' strips which are difficult for the child to undo and make him more likely to take only one tablet at a time Unfortunately, the present competitive prices make such expensive packing impracticable for the manufacturer unless a policy could be agreed by all manufacturers

The only real safeguard is for all tablets to be kept in locked containers

Addendum

Since this paper was written Grainger (1958) has reported an experiment using different coloured sweets He came to the conclusion that children preferred the coloured to the white ones, but his experimental method was open to criticism, and this was raised by correspondents in the following two numbers of the same journal

We are indebted to Glaxo Laboratories Ltd for the coloured tablets

ACUTE CASE OF WILSON'S DISEASE

(HEPATOLENTICULAR DEGENERATION)

N R LAWRIE
Ph D Cantab, M B Lpool
UNIVERSITY BIOCHEMIST, ADDENBROOKE'S HOSPITAL, CAMBRIDGE

R A CARTER
M.A, M B Cantab, M R C P
JUNIOR ASSISTANT PATHOLOGIST, UNIVERSITY OF CAMBRIDGE

IT is now generally realised that hepatolenticular degeneration varies greatly in its speed of progression (Wilson 1912, Hall 1921, Raskin and Mackenzie 1956, Walshe 1956a, Bearn 1956) and in the relative prominence of neurological and hepatic symptoms (Bickel et al 1955)

Walshe (1957) has reviewed Wilson's disease with particular reference to the biochemical lesion and has critically discussed the current theories of the pathogenesis of this disease

The great majority of reports of the treatment of this condition are confined to the more chronic neurological cases Acute cases seem to be altogether less common, but this may only reflect the greater difficulty in recognising the syndrome We therefore report here the course of such an illness

Case-report

A boy, aged 12 years, was admitted to Addenbrooke's Hospital on Dec 29, 1955, with two weeks' history of malaise and anorexia He had pain in both knees, and his parents said that his legs were swollen Up to the time of this illness he had apparently been in good health

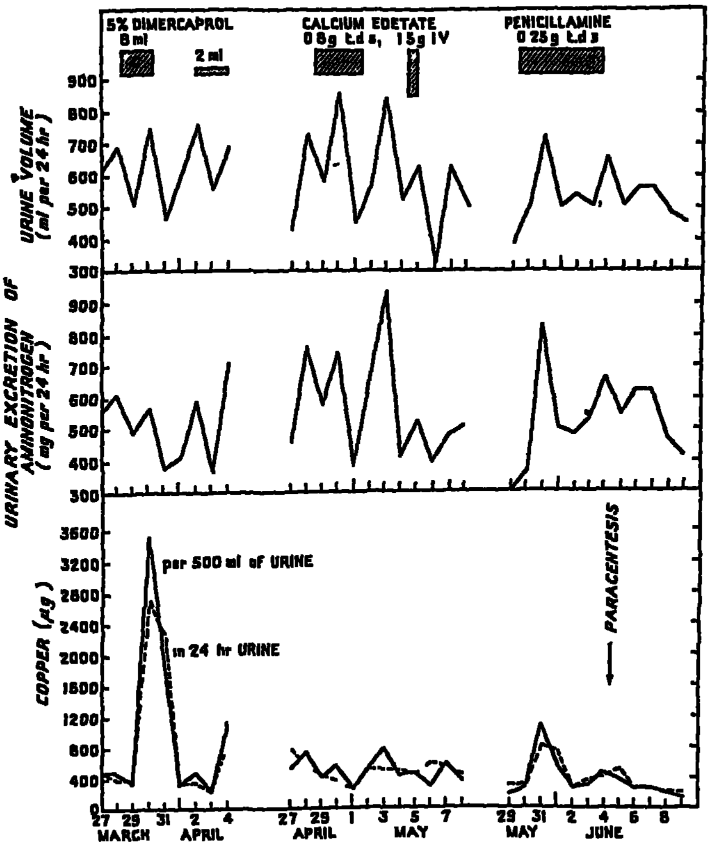
Family history—His parents are first cousins and both are healthy, as are his two surviving brothers A brother who died at the age of 18 was reported to have had "paralysis" for four or five years after a head injury of unknown severity and finally to have died with "fits" Inquiry has not thrown any further light on this illness, it may be compatible with a diagnosis of Wilson's disease but it is not conclusive

On examination the patient was pale, ill, and apprehensive, and did not speak or smile He had conspicuous œdema of his legs and sacrum, and considerable abdominal distension, with much free fluid in the abdominal cavity His liver and spleen could not be felt Signs of a moderate pleural effusion were present at the base of his right lung

Investigations—Radiography revealed œsophageal varices and probably gastric varices also The serum-protein level was 6 0 g per 100 ml, and paper electrophoresis showed an extreme deficiency of albumin and a considerable excess of γ-globulin The serum-bilirubin level was 0 6 mg per 100 ml, serum-cholesterol 200 mg per 100 ml, and serum-uric acid 2 0 mg per 100 ml The thymol flocculation test was negative, thymol turbidity 10 units, and alkaline phosphatase 7 8 Bodansky units The prothrombin content of the plasma was 21% of the average normal by Quick's one-stage method Symptomatic treatment for eight weeks having produced little clinical improvement, the patient's urine was collected for twenty-four hours with due precautions against contamination by copper This contained 166 μg of copper, an abnormally high value but not above the figures cited for some adult cases of cirrhosis, not clinically Wilson's disease, by Cartwright et al (1954) and Bearn and Kunkel (1954) However, the serum-paraphenylenediamine-oxidase activity was 2 Bearn units (Bearn and Kunkel 1954), the normal range being 2 3–5 2 units, and cases of ordinary cirrhosis showing a raised or high normal activity (3 5–13 2 units) The urinary excretion of aminoacids was 0 47 g per twenty-four hours, a high value for a child aged 12 years, electrophoresis and chromatography revealed an unusual aminoacid pattern in which histidine, tryptophane, lysine, aspartic acid, hydroxyproline, cystine, methionine, alanine, phenylalanine, glycine, valine, and leucine were increased in amount, and threonine and citrulline were present in conspicuous amounts (Taurine was present in normal amounts)

Diagnosis and treatment —On these findings Wilson's disease was diagnosed, and therapy with dimercaprol was begun During the second course of this treatment the patient's daily output of urine decreased to 35 ml , and dimercaprol was withheld at once No other toxic effects were noted No clinical benefit was observed from this limited period of treatment, but much more copper was excreted (see figure) After four weeks' rest, in which no clinical change was observed, treatment with calcium edetate was followed by a slight increase in the output of copper After four weeks penicillamine was given (Walshe 1956a and b) The initial increase in excretion of copper was poorly maintained, and the child, now severely ill, showed no improvement The urinary output of aminoacids, unchanged by treatment with either dimercaprol or calcium edetate, increased during, and for some time after, penicillamine therapy, probably because penicillamine is an aminoacid which is excreted largely unchanged During this period an extra band, having the same mobility as penicillamine, appeared in electrophoretic separations of urinary aminoacids

Course —During the five months' treatment in the ward this child had remained uncommunicative, with conspicuous lack of facial expression, indicating profound emotional disturbance. He was apt with his hands and fully aware of what went on in the ward When interfered with, he was liable to outbursts of fighting and screaming However, none of the neurological findings more usually associated with Wilson's disease were in evidence Tremor was never detected He developed spider nævi on his hands and face and conspicuous gynæcomastia Kayser-Fleischer rings, hardly visible at first to the naked eye, were clearly seen on slit-lamp examination A mild diplopia was also detected Paracentesis was done for ascites on three occasions On June 18, 1956, the boy lapsed into coma and died Details of treatment and of urinary excretion of copper and aminoacids are given in the accompanying figure



Treatment and urinary excretion of copper and aminoacids

Necropsy findings —The body was that of a wasted male child weighing 39 kg , with ascites and with pitting œdema of the ankles and thighs The liver was small (985 g), studded with yellowish nodules up to 0 6 cm in diameter The cut surface showed nodules throughout the substance of both lobes The spleen was enlarged (625 g) and had a firm solid pulp Œsophageal varices were present The outer and cut surfaces of the brain revealed no obvious abnormality, and no cavitation was seen in the basal ganglia

Microscopy —The liver showed severe fibrosis with regeneration nodules, some cells showing recent acute degeneration, and there was conspicuous infiltration with chronic inflammatory cells The picture resembled subacute hepatitis with continuing necrosis The basal ganglia showed a probable loss of neurones and an increase in glia, with pallidal siderosis, and fibrillar structures, probably microglial processes, which stained strongly with stains for copper No abnormality was seen in any other section of the central nervous system In the cornea pigment granules, histochemically containing copper, were seen in the membrane of Descemet, towards the limbus, confirming the presence of the Kayser-Fleischer rings Apart from the Kayser-Fleischer rings the histological findings were not specific for Wilson's disease, but the presence of much copper in the tissues was demonstrated both histochemically and by bulk analysis The histochemical techniques are described in the appendix (see below)

Discussion

The unusual features of this case are as follows

(1) *The absence of tremor and neurological signs* —The emotional behaviour, expressionless face, and paucity of speech were probably facets of the disturbance in Wilson's disease, but they are in themselves too indefinite to be regarded as signs of involvement of the central nervous system

(2) *The absence of diagnostic pathology in the basal ganglia* —Such cases have been reported before (e g , Raskin and MacKenzie [1955]) and some of the changes in the ganglia (e g , the copper-positive glial fibres) may be more specific than we at present realise

(3) *The short duration of the illness* —Several such cases have been published since the original description of Ormerod's case (Wilson 1912)

It therefore seems that this is a true case of Wilson's disease in which the liver dysfunction has dominated the clinical picture, and the disease has been so acute that the changes in the basal ganglia have not had time to reach cavitation before death This case is similar to case 12 described by Bickel et al (1957), who also describe two cases similar to the present case in that the Kayser-Fleischer rings were only discernible on slit-lamp examination Chalmers et al (1957) describe five cases of an " abdominal " form of Wilson's disease in which there were no significant neurological findings, and there seems to be little doubt that the present case belongs to this group

In the present case, of the three agents at present available for therapy, dimercaprol seemed to be the most effective, but it necessitated frequent painful intramuscular injections, it is also very toxic and must be used with caution Calcium edetate appeared to be relatively ineffective and, in view of the trouble of intravenous infusions, is clearly unsuitable for long term therapy

Penicillamine may offer a good alternative to dimercaprol, especially where injections at short intervals are impracticable. Walshe (1956a) and Osborn and Walshe (1958) compare it very favourably with dimercaprol Our findings as regards the relative efficacy of dimercaprol, calcium edetate, and penicillamine in promoting urinary excretion of copper are most unusual The case, however, was of a very exceptional type, and the disease was nearing a fatal termination when calcium edetate and penicillamine were tried Intravenous infusions of coeruloplasmin have been tried (Bickel et al 1957), but their clinical value is not yet clear

Summary

An acute case of Wilson's disease is described, together with the necropsy findings Minimal involvement of the central nervous system was associated with an excessive urinary excretion of copper and aminoacids, and a low serum-paraphenylenediamine-oxidase activity Treatment with dimercaprol greatly increased the copper output, calcium edetate and penicillamine being less effective.

We wish to thank Dr D Gairdner and Dr J D Roscoe for permission to publish and for advice on the presentation of the clinical material, Dr A M Barrett for his help with the histology, Mr G C Spurgeon for technical assistance in the preparation of the histological material, and the Distillers' Co Ltd for a gift of penicillamine

Appendix

Methods

Copper was estimated by a slight modification of the method of Eden and Green (1940), with due care to avoid contamination We obtained duplication of analyses within ±4% of their mean, and a reagent blank of not more than 1 μg of copper

Cœruloplasmin was estimated by the method cited by Bearn and Kunkel (1954)

Total aminonitrogen was determined by the method of Albanese and Irby (1944) Urinary aminoacids were studied by zone electrophoresis and by two-dimensional chromotography

Material for histochemical study was fixed in neutral buffered formol saline (pH=7·0), prepared with analar reagents, and containing 31μg of copper per litre The hæmatoxylin technique of Mallory and Parker (1931) was used to search for excessive copper, since this technique is of rather doubtful specificity, positive material was then stained with 0·5% rubeanic acid in ethanol and with 1% dithiosemicarbazone in citric-acid solution Positive reactions with all three stains were obtained in liver, cornea, and basal ganglia.

"Dr Betts found when he visited patients, that when he seemed to be in great haste, they used to detain him long upon some frivolous questions, and when he took no great notice but began to ask questions himself, they never endeavoured to stay him, by which practice his visits were but short, wherever he came"—Journal-Book of the Royal Society for June 19, 1700 *Notes and Records of the Royal Society of London*, 1951, 8, 157

POPLITEAL EMBOLECTOMY
WITH RETROGRADE FLUSHING VIA THE POSTERIOR TIBIAL ARTERY

G E Mavor
M.A., Ch.M Aberd., M.D Rochester, F.R C S.E
SENIOR SURGICAL REGISTRAR, ABERDEEN ROYAL INFIRMARY

The conservative approach to the treatment of peripheral arterial embolism has inherent limitations For instance, such treatment is usually deemed successful if the limb is saved, though generally under such circumstances residual ischæmic symptoms persist and may be severe On the other hand, successful embolectomy has a more satisfactory end-result, as the limb is returned to normal When embolectomy is unsuccessful it is usually because it is undertaken too late, after distal arterial thrombosis has begun, aided perhaps by fragmentation of the embolus Under these conditions Shaw (1956) has shown that a more aggressive surgical approach is necessary This entails opening the artery distally and flushing it out retrogradely with heparin in saline solution

I here report a case of popliteal-artery embolism with distal thrombosis which was successfully treated in this manner

Case-report

A man, aged 51, entered hospital because of severe pain, of seven hours' duration, in the left popliteal fossa The pain was of sudden onset, and spread to become generalised over the upper calf He noted intense pallor, coldness, and numbness of his foot He could not walk and latterly had had some difficulty moving his toes He had had atrial fibrillation, complicating rheumatic heart-disease, for several years

Examination—His pulse was irregular (rate 96 a minute), and blood-pressure 150/78 mm Hg A systolic murmur was present over the cardiac apex The left leg was cold and cyanotic from midcalf level, with diminished sensation over this area Although active movements of the toes and ankle were possible, weakness was obvious, both of dorsiflexion and plantarflexion The left femoral and popliteal pulses were easily palpated, but both anterior and posterior tibial pulses were absent On the right side the peripheral pulses were present

Treatment—Anticoagulant therapy was begun and peripheral vasodilatation encouraged by sedation, the administration of whisky, and heating the trunk and hands After three hours there was no improvement in the condition of the left leg, the skin temperature fell 5°C during this period. Operation was undertaken

Operation—Under general anæsthesia the left popliteal artery was exposed and opened about 2 inches above its bifurcation. Good bleeding was obtained from the proximal end but none from the distal end Suction via polyethylene tubing was without effect The posterior tibial artery was then exposed at the ankle and opened No clot was present By use of a 50 ml syringe, retrograde flushing was carried out with heparin in physiological saline solution (10,000 units heparin per 500 ml) Small fragments of clot escaped via the popliteal arteriotomy 300 ml of solution was used. Both arterial incisions were then closed Before skin closure, no pulse was palpated in the posterior tibial artery At the end of operation the condition of the leg had greatly improved. There was no

Arteriogram ten weeks after embolectomy, showing patent popliteal and proximal anterior and posterior tibial arteries cyanosis or pallor, the foot and toes being of good colour Neither anterior nor posterior tibial artery could be palpated

Postoperative progress —The condition of the patient's foot remained satisfactory, and the posterior tibial pulse was palpable on the seventh postoperative day, but some weakness of dorsiflexion of the foot persisted Anticoagulant therapy was begun on the seventh postoperative day, and was continued for two months An arteriogram ten weeks after operation showed that the popliteal and posterior tibial arteries were patent (see fig 1) The anterior tibial artery was blocked about midcalf level Six months after operation weakness of dorsiflexion persisted There were no other complaints

It seems likely that the return of an adequate peripheral circulation was due to the retrograde flushing with removal of fragments of embolus and propagated thrombus from the posterial tibial artery The persistent weakness of dorsiflexion of the ankle may have resulted from damage to the lateral popliteal nerve during operation or may have been the result of ischæmia The former was not considered likely since the nerve in question was neither stretched nor damaged at operation The possibility of ischæmic damage was suggested by the postoperative arteriographic findings This underlined the need for retrograde flushing of the anterior as well as the posterior tibial artery in similar circumstances

Discussion

The exact place of surgery in the treatment of peripheral arterial embolism is a matter of some dispute The advent of the anticoagulant drugs laid emphasis on the conservative approach, which was furthermore often held justified because of the poor results of late surgery—notwithstanding the knowledge that the results of surgery were better the earlier embolectomy was undertaken It is wise in early cases to initiate conservative measures, but these must be abandoned for surgery if after two to three hours the peripheral circulation has failed to improve In late cases there is the added possibility of the presence of distal propagated thrombus, and indeed the likely presence of such clot has been regarded as justifying a refusal to operate

It is now apparent that by means of retrograde flushing some cases may be retrieved after the lapse of over twenty-four hours from the onset of ischæmia, and even where gross ischæmic changes, such as anæsthesia and complete loss of power, are present (Shaw 1956) This procedure was first described by Lerman et al (1930), and was revived by Shaw and by Crawford and DeBakey (1956) Shaw has applied it with success in late cases of acute thrombosis as well as embolism, in one instance thirty-three hours after the onset of severe ischæmic changes in the limb

With few exceptions only surgery can restore the limb to normal in cases of acute arterial insufficiency due to embolism or thrombosis, and, even after delay has led to considerable deterioration in the limb, operation may still restore the peripheral circulation

Summary

A case of embolism of the popliteal artery was treated by popliteal and posterior-tibial arteriotomies with retrograde flushing to remove emboli and propagated thrombus

Adequate circulation was restored

Medical Societies

AMERICAN GASTROENTEROLOGICAL ASSOCIATION

THE Association's 59th annual meeting was held, under the chairmanship of Dr **CLIFFORD J BARBORKA** (Chicago, Ill), at Washington on May 30 and 31

Bilirubin Metabolism

Dr **RUDI SCHMID** (Boston, Mass) traced bilirubin production from the breakdown of a red blood-cell at the end of its 120-day lifespan The protoporphyrin ring is broken open to yield biliverdin, and this in turn yields free bilirubin, which is insoluble Solubility is achieved after passage through the liver, which conjugates one molecule of the compound with two molecules of glucuronic acid The insolubility of the free form and the solubility of the diglucuronide form of bilirubin account for the indirect and direct van den Bergh reactions The insoluble free form cannot be excreted by the kidney, hence in hæmolytic anæmias jaundice is acholuric since only the free form is present in excess Congenital non-hæmolytic jaundice is due to an intrahepatic enzymatic defect causing failure of conjugation of free bilirubin with glucuronic acid, as can be demonstrated in a strain of rats subject to this defect Jaundice of the newborn may be due to delay in development of the same mechanism

Dr **IRWIN M ARIAS** (New York) outlined the enzyme system responsible for the conjugation of bilirubin within the liver Glucuronic acid is mobilised by a transferase from uridine diphosphate glucuronic acid (U D P G A) This system has many applications, it is the method of transporting and excreting salicylates, which patients with the rare congenital condition of non-hæmolytic jaundice cannot metabolise

Dr **KURT ISSELBACHER** (Boston, Mass) pointed out that the U D P G A transferase system has many purposes either for detoxification by rendering substances physiologically inactive, or for making substances soluble, the corticosteroids, the sex hormones, thyroxine, morphine, and adrenaline are metabolised by the system—and serotonin to a lesser extent Glucuronide is formed from glycogen and glucose and becomes attached to uridine diphosphate

Dr **JESSE L BOLLMAN** (Rochester, Minn) referred to the monoglucuronide form of bilirubin which is found in the serum of dogs after removal of the liver when the diglucuronide is of necessity absent After experimental damage to the liver following administration of carbon tetrachloride, diglucuronide is much reduced and monoglucuronide proportionally increased The ratio of the di- to the mono- form—normally 3 to 1—may provide a basis for a diagnostic test in cases of jaundice In obstructive jaundice liver cells still function and an abnormally high proportion of diglucuronide can be demonstrated, whereas in hepatitis the proportion of diglucuronide is abnormally low In chlorpromazine jaundice there is a preponderance of monoglucuronide, suggesting hepatocellular damage rather than obstruction due to œdema of the intrahepatic ducts The presence of monoglucuronide after liver extirpation in dogs seems to suggest an extrahepatic site of conjugation

Assessment of Liver Function

Dr **NORBERT HENNING** (Erlangen, Germany) assesses portal circulation-times by duodenal instillation either of an acetylene derivative from which acetylene is metabolised by the liver and excreted from the lungs and can then be estimated in the expired air, or of ^{131}I, the rate of decrease in radioactivity over the duodenum then being determined An increased portal pressure can be revealed by the pressure at which rectal mucosa blanches on direct contact through a sigmoidoscope Alternatively the amount of heat which may be reabsorbed through a thermocouple in contact with colonic mucosa from a source of heat applied to the mucosa at a point nearby is directly proportional to the portal flow

Dr E Englert (Boston, Mass) has been using radioactive rose-bengal to study uptake in liver from the blood, liver storage, and excretion

Dr E Pineda (Boston, Mass) showed how the enzyme β-glucuronidase in the serum increases in hepatitis and falls below normal levels in liver failure, while Dr K S Henley (Ann Arbor, Michigan) has devised a technique for studying liver parenchymatous cells alone to the exclusion of the Kupfer cells and thus the enzymes glutamic oxalacetic transaminase and glutamic pyruvic transaminase, his work indicates that G P T is a more sensitive guide to hepatic dysfunction than is G O T

Dr F Wroblewski (New York) observed that changes of enzyme level in the serum do not reflect liver necrosis, nor liver function generally

Dr G Jerzy Glass (New York), using radioactive vitamin B_{12}, has shown that the greatest bodily store of this vitamin is in the liver, where the substance is in greater concentration than elsewhere, vitamin B_{12} is stored to a far lesser extent in the kidneys

The Pancreas

Opening a symposium in memory of the late Dr Mandred W Comfort, Dr Paul Nemir (Philadelphia, Pa) said that he has found that interstitial non-lethal pancreatitis follows the experimental intraperitoneal injection of activated pancreatic juice obtained from an isolated jejunal loop, it also follows injection of mixtures of pancreatic juice and organisms such as *Clostridium welchii* and *Escherichia coli* By contrast, activated pancreatic juice mixed with blood is highly toxic, and on injection causes lethal acute necrotising pancreatitis From this Dr Nemir inferred that in man pancreatitis becomes severe when vascular damage to the gland permits the escape of blood which then comes into contact with the enzymatic action of the liberated pancreatic juices

Dr Henry Janowitz (New York) has found that the trans-sphincteric rate of flow of pancreatic juice following secretin injection in patients with chronic pancreatitis, half of whom had radiological evidence of calcification in the gland, was not substantially less than in a control group of patients There was therefore little evidence to indicate ductal obstruction Dr Morton Grossman (Los Angeles, Cal) challenged this conclusion, since partial obstruction has been shown physiologically not to decrease but rather to increase the rate of flow

Dr John Budd (St Louis, Missouri) compared the urinary-diastase and serum-amylase levels in different pancreatic conditions Though in acute pancreatitis there is parallelism between the two initially, the diastase in urine remains increased longer, so this test may be used as an indication of persistence of the disease In hæmorrhagic disease, only the urinary diastase may be affected—and that at a later stage Estimation of urinary diastase has a place, therefore, as a clinical test in pancreatic disease

Gastrointestinal Motility

Two new techniques for studying gastrointestinal motility were described

Dr G Vantrappan and his colleagues (Chicago, Ill) have been able to obtain simultaneous fluorocinematography pictures and a record of intraluminal pressure on the same screen, and so to be certain of the type of peristaltic wave change inducing pressure changes This technique has been used to study normal deglutition, tertiary œsophageal contractions, and diffuse spasm of the œsophagus

In the second new technique (Dr J T Farrar [New York]) intraluminal pressures are recorded by the use of an ingestible, pressure-sensitive radiotelemetering capsule, or " radio pill " The capsule, 3 cm long and 1 cm in diameter, contains a replaceable battery lasting twenty-four hours, a frequency-modulation transistor radio transmitter, and a pressure-sensitive diaphragm Pressure change transmits signals to a frequency-modulation receiver, displayed on an oscilloscope and recorded on paper It has been found possible to obtain records from stomach, small intestine, and right colon which correlate well in frequency and appearance with those recorded by other methods This technique has a particular place in the study of functional disorders of small and large bowel over long periods

Dr Charles Code (Rochester, Minn.) spoke of the enormous potentialities of both methods

Carcinoidosis

In the Association's annual memorial lecture, Prof Jan Waldenström (Malmo, Sweden) discussed 156 cases of carcinoidosis He stressed the predilection of the endocardial lesions for the right side of the heart, the frequencies of valvular involvement being pulmonary 35, tricuspid 36, mitral 12, and aortic 4 He also produced histological evidence that the endocardial lesion is biochemically induced He described a case of carcinoidosis in which the primary tumour existed in a teratoma In some instances a severe pellagra-like syndrome is associated with the clinical picture, and Professor Waldenström suggested a possible biochemical reason for this association The antiserotonin drugs have proved disappointing, and no medical treatment is of value, surgical excision offers the only hope of remission

Effects of Serotonin on Gastrointestinal Tract

Dr B J Haverback (Los Angeles, California) said that serotonin and its precursor 5-hydroxytryptophan powerfully stimulate intestinal motility—an effect which is potentiated by lysergic acid diethylamide and inhibited by bromlysergic acid diethylamide and histamine-releasing substances Normal ranges of blood-serotonin and urinary 5-hydroxyindoleacetic-acid levels are 0 15–0 5 µg per mg of platelet protein and 2–9 mg per 24 hr respectively Studies on patients who had undergone intestinal resection suggest that the gastrointestinal tract makes a major contribution to the blood level and urinary output of serotonin

In the ensuing discussion it was pointed out that the urinary excretion of 5-hydroxyindoleacetic acid is temporarily increased after eating bananas, which contain large amounts of serotonin, that it is increased in the patient with idiopathic steatorrhœa in relapse, which is thus distinguishable from other types of steatorrhœa in which the urinary levels are normal Remissions induced by the gluten-free diet are accompanied by a decrease in the urinary elimination of 5-hydroxyindoleacetic acid to normal levels Raised urinary levels have also been observed in some patients with schizophrenia

Diverticulosis

Dr R S **Boles** and Dr S M **Jordan** (Boston, Mass) described a study of 294 patients with diverticulosis who were followed for between ten and thirty-one years 25% later had diverticulitis, and 6% developed symptoms attributable to diverticulosis—namely, obstruction, bleeding, and fistula formation While obstruction seems to be statistically related to the number of attacks of inflammation, bleeding and perforation seem to be unrelated to the number of attacks Cancer developed in 5% of patients with uncomplicated diverticulosis, in 3 6% of those with diverticulosis associated with complications, and in 6 8% of those with diverticulitis, but the correlation was not clear, and cancer commonly developed in areas unaffected by disease

Antibiotics

In a critical bacteriological appraisal of antibiotics for colon surgery, Dr I **Cohn**, Jr (New Orleans, Louisiana), found most of the drugs usually recommended—particularly sulphonamides—unsatisfactory in the control of the intestinal flora

He recommended a combination of neomycin and achromycin, and has obtained good results by injecting the antibiotics down a fine plastic tube to the anastomosis site

Regional Enteritis

A panel consisting of Dr J A **Bargen** (Rochester, Minn), Mr B N **Brooke** (Birmingham, England), Dr R B **Cattell** (Boston, Mass), Dr J B **Kirsner** (Chicago, Ill), and Dr F E **Templeton** (Seattle, Washington), with Dr B B **Crohn** (New York) as chairman, discussed regional enteritis

The ætiology of the condition remains obscure Familial examples of the condition have been reported, but heredity plays only a minor role Mesenteric glandular enlargement seems to be secondary rather than primary It is largely a disease of young people, in a large series the average age was 27 3 (range 4–74), it runs a long course and often recurs after operation—in fact, in the Mayo Clinic series 135 out of 400 patients had had recurrences after two to six years, and these recurrences were commonest in young people The ten-year-survival rate was 81%

Radiographic identification of the disease is extremely difficult, but with care is possible in 50% of cases Serial thirty-minute films after oral administration of flocculating barium suspension was recommended, but terminal ileum can usually be better displayed by a barium enema The stenosing lesion is easily identified, but other forms are difficult to detect The deficiency pattern and cobblestone mucosal change, though often helpful, are nonspecific

Mr Brooke described the distribution of the initial lesions in 121 patients these were duodenal or jejunal 14, ileal 48, ileocæcal 40, colonic and ileal 12, and colonic alone 7, thus 62 had ileal lesion alone, and 59 combined involvement of small and large bowel

As to treatment it was generally agreed that medical treatment should be applied initially, and surgery reserved for the complications of obstruction and fistula formation Bed rest, high-protein high-calorie diet, hæmatinics, blood-transfusion, and electrolyte replacement were recommended Neomycin or achromycin often relieve fever and toxicity, steroid therapy sometimes induces dramatic remissions, and it has not, in the panel's experience, induced perforation Dr Bargen has had good results from X-ray therapy in two to three courses of 600r

The surgical members of the panel asserted that medical treatment has never effected a cure, but surgery was still to be used only for the complications of the disease—resection was preferred to a bypassing operation A recurrence-rate of 34% was to be expected, but two-thirds of the patients treated at the Lahey Clinic and the Mount Sinai Hospital have had successful results from surgery In acute regional enteritis simulating appendicitis, the appendix should not be removed, appendicectomy predisposes to fæcal fistula Recovery ensues in the majority of these acute cases, which do not necessarily progress to the chronic form Before attempting to deal with perianal disease, a common complication, it is necessary to correct the intestinal defect Associated liver disease and carcinoma were regarded by most members of the panel as exceedingly rare

---

New Inventions

AN AUTOMATIC CAMERA FOR USE IN OPERATING-THEATRES AND WARDS

This automatic camera can provide a day-and-night colour-photographic service in operating-theatre and ward and requires no skilled assistants for its operation The camera unit is positioned by an unsterile assistant under the direction of the surgeon, who controls by a foot-switch both the camera shutter and the focusing torches, which work on the range-finding or " dam-buster " principle

Apparatus

The camera unit, made of 'Perspex', is airtight to enable it to be used during the administration of all types of anæsthetic,

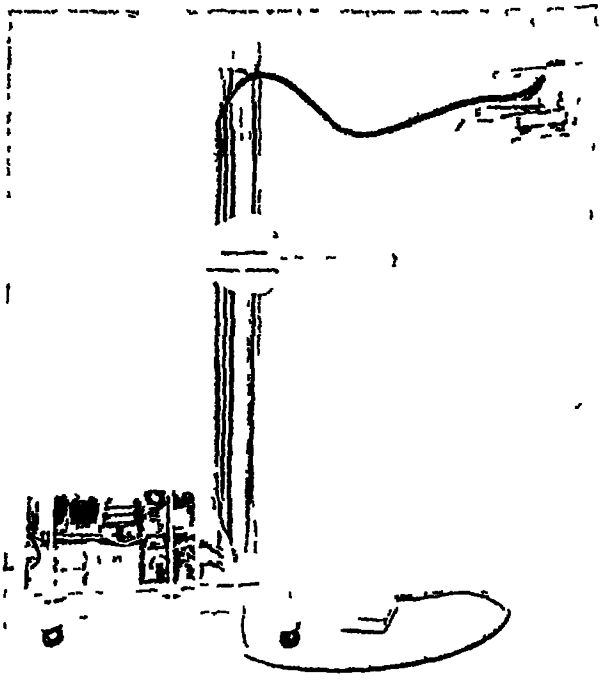

Fig 1—Automatic theatre camera

This is mounted on a stand similar to that used by mobile X-ray machines The camera unit is on an adjustable arm that can be swung over the operating-table The power pack on the base of the stand acts as a counterweight The foot-switch has two buttons, one switches on the focusing lights, the other operates the camera shutter it includes an electronic flash-tube and two pairs of focusing lights and is mounted on a stand similar to that used in mobile X-ray machines (fig 1) Mounted also in an airtight box on the stand is the power supply

The camera is a 'Robot' using 35 mm. film. In this camera film transport and shutter setting are done by clockwork, the foot-switch operates the shutter release through a solenoid (fig 2) Twenty-four exposures can be made before the camera clockwork has to be rewound.

The telephoto lens covers a field of $4^1/_2$ inches square at the near setting and 8 inches square at the distant setting Photographs are taken only in these two positions, the desired size of field being selected by manipulating a knob on top of the camera unit.

Each pair of torches is preset and fixed so that their light beams intersect, one pair at the near focus and the other at the distant focus of the camera lens, and illuminate the respective fields covered by the lens at each of these settings (fig 2) The wiring of the torches is arranged so that the appropriate pair is lit when the "focus" button on the foot-switch is depressed.

To take a photograph during an operation the camera unit is placed above the object, and the surgeon directs its raising or lowering until the focusing beams intersect on the object (fig 3), he can then take up to 24 photographs simply by pressing the "take" button on the foot-switch.

Illumination for the photograph is provided by a 310-joule electronic flash housed in an airtight reflector and arranged in a circle around the lens (fig 4) This arrangement gives intense illumination even in deep cavities and allows small lens-apertures to be used It thus gives a good depth of focus of about 4 inches on the small field and 6 inches on the large.

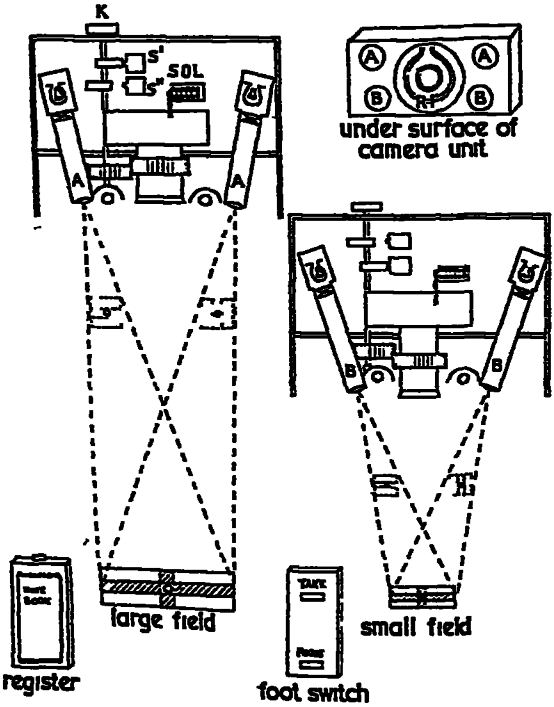

Fig 2—Construction of camera unit and focusing arrangement for two sizes of field A, torches for large field, B, torches for small field, operated by foot-switch 'focus" button, RF ring flash.

Knob K on top of camera unit adjusts lens focus, at each extreme of this movement switches S^1 and S^{11} operate so that appropriate pair of torches are lit when foot-switch button focus' is depressed When light beams intersect on object, surgeon depresses foot-switch button 'take", this energises solenoid (SOL) and operates camera shutter Clockwork mechanism in robot camera transports film and sets shutter for next exposure Up to 24 consecutive photographs can be taken in this way To ensure that subject matter of each photograph is recorded a switch is arranged so that apparatus will not work until lid of register has been raised.

An electrical device helps to ensure that details of each patient are entered in the record book kept under a hinged lid on top of the power pack, because when switched on at the mains the machine will not work until this lid has been raised

Results

Definition is of a high order because of the high optical quality of the lens, and because blurring from movement and vibration is eliminated by the extremely short duration of the flash —12 microseconds Colour values are constant, and it is not difficult to photograph such objects as the vagus isolated during an abdominal vagotomy

Advantages

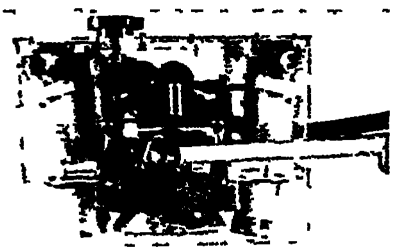

Fig 3—Torches act as rangefinders and enable camera unit to be placed at correct distance from object.

Each pair of torches is preset and arranged so that their beams intersect, one pair at near focus and other pair at distant focus of lens, and illuminate respective camera fields at each of these settings Torches are wired so that appropriate pair is lit when "Focus" button on foot-switch is depressed

Other arrangements for automatic photography in the operating-theatre have disadvantages with cameras in fixed positions, like that of the operating-lamp, it is difficult to arrange for more than one size of photographic field and, unless a flash unit is included, colour photography is impracticable, moreover, such a camera cannot easily be moved to another theatre, ward, or clinic and cannot even easily be used to photograph specimens removed at operation.

Photographic arrangements relying on a photographic technician are invariably subject to delay, and, unless a special gantry is available, it is often impossible for the photographer to reach the best vantage point above the sterile operation field.

The apparatus here described fulfils most of the desiderata and meets both clinical and medicolegal needs in all types of hospital

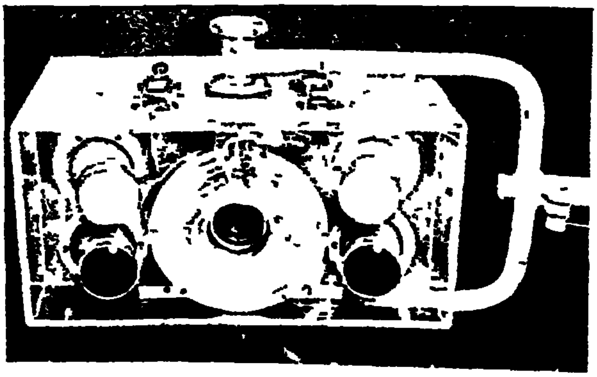

Fig 4—Undersurface of camera unit, showing two pairs of torches (one pair illuminated) and camera lens surrounded by reflector housing the ring-shaped electronic flash-tube

The prototype was built by kind permission of Dr R G Macfarlane, F R S, in the Nuffield hæmatology workshop, Radcliffe Infirmary, and the apparatus is now in commercial production I wish to thank Dr Macfarlane and Dr F Kemp for facilities, Mr E J Burrough and Prof T P Kilner for arranging financial assistance, and Mr A Lord for building most of the prototype

SPECIFICATION

Camera—Robot 2 A or ' Star ' Negative-size 24 mm x 24 mm on 35 mm colour film (' Kodachrome ') (30 exposures on normal 20 exposure length)

Lens—Schneider ' Tele-Xener ' 7 5 cm Iris diaphram aperture is adjusted automatically to f 14 for near focus and f 11 for distant focus

Flash—Ring-type 312-joule (fig 4)

Torches—Preset 48 watts each Contains lens systems and masks giving beams as shown in fig 2

Camera unit and power pack—Are mounted in airtight ' Perspex ' boxes

Focusing mechanism—By means of a gear the focusing-knob on top of the camera unit operates the focusing ring on the lens This is used only at each extreme of its focusing range In these positions the appropriate pair of torches is brought into circuit

Servicing—By releasing four clips the camera, together with the lens and electronic flash tube, can be easily removed from the rest of the camera unit for servicing

Reviews of Books

Thinking

An Experimental and Social Study SIR FREDERIC BARTLETT, C B E, F R S, formerly professor of experimental psychology and director of the psychological laboratory, University of Cambridge London Allen & Unwin 1958 Pp 203 18*s*

So deeply dualistic are our basic assumptions about the nature of human behaviour that the suggestion that the skills of the mind have some features in common with the skills of the body may at first seem bizarre Sir Frederic, however, not only has been so open-minded as to invent such a hypothesis, but has been ingenious enough to test it The first chapters report the findings of his experiments on the formal processes of thinking, on interpolation and extrapolation, thinking stepwise and by intuitive jumps The significance of direction, sequence, and dependence on social background are illustrated Moving from the laboratory to the field and from " closed " to " adventurous " thinking, later chapters deal with thinking of the experimental scientist, of the artist, and of the man-in-the-street These activities are delineated with delightful originality and clarity so that many things we have vaguely or confusedly been aware of suddenly jump into focus

Thinking presents a distillate of years of reflection and investigation in a way which will interest both those pursuing research in the same field, and the rest of us who practise daily, willynilly and as best we may, the very kinds of behaviour described It is a quarter of a century since Sir Frederic's *Remembering* was published and many of its fruits are still ripening *Thinking* and also *The Mind at Work and Play* (which preceded it by seven years) will help to mature and extend the already abundant harvest Sir Frederic has made a splendidly growing and growth-promoting contribution to our understanding of human behaviour

A Centenary of International Ophthalmology (1857-1957)

SIR STEWART DUKE-ELDER, K C V O, F R C S London Henry Kimpton 1958 Pp 91 12*s* 6*d*

THE centenary meeting of the International Congress of Ophthalmology is being held this year in Brussels, where the first congress took place The ophthalmoscope had been demonstrated by Helmholtz in 1850 to the Physical Society in Berlin, and, by allowing the exploration of the inner eye for the first time, completely changed the scope and outlook of the specialty, a new science had been created, the implications of which were of immediate practical importance But in 1857 it was still not widely known and those who used it were being confronted almost daily by unsuspected clinical pictures which were new and difficult to interpret It seemed urgent, therefore, to extend the use of the instrument as widely as possible, and equally important that those who were already becoming familiar with it should meet together to collate their observations and agree on their meaning and significance It was therefore decided to hold an international congress

Sir Stewart's book tells something of the story of international ophthalmology in all its aspects, and it reflects exciting highlights in the advance of the subject The salient features of each meeting are briefly described, and most accounts are preceded by a small portrait of the president, including Fallot, von Graefe, Argyll Robertson, Snellen, and Sir Stewart himself The latter part of the volume deals with the work of the International Council of Ophthalmology, and ends with some wise remarks about the future of the Congress

Methods in Enzymology

Vol 4 Editors S P COLOWICK and N O KAPLAN London Academic Books 1957 Pp 914 £8 11s 6d

THE final instalment of this ambitious publication maintains the high standard of the preceding volumes The opening section gives an admirable survey of the principal methods used in the characterisation not only of enzymes but of proteins generally The first article is on electrophoresis and is by Arne Tiselius himself The middle section of the book, much the shortest, is a miscellany entitled Techniques for Metabolic Studies The articles by Britton Chance on spectroscopic observation of respiring cell-particles and that by O H Lowry on micromethods of enzyme assay are of outstanding interest In a contribution on histochemical methods it is disappointing to find not even the briefest general appraisal of this approach to cellular biochemistry On the other hand, the article by F S Sjöstrand on electron microscopy of cellular constituents (unexpected in such a context) is a very valuable review

The rest of the book is devoted to isotope techniques Here again the introductory articles (by D Sternberg and S Udenfriend on radioactive tracers and by A San Pietro on stable ones) are admirable The contributions which follow record radiochemical methods for the synthesis and degradation of compounds important in intermediary metabolism The article on the isolation of Krebs-cycle intermediates overlaps to some extent one dealing with the same substances (unlabelled) in the third volume, but the rarity of such overlap in a work of some 4000 pages is a tribute to the editors

Methods in Enzymology provides a valuable starting-point for anyone seeking information on practical problems in this and related fields of biochemistry, and it is also for many purposes a useful bench manual

---

Medicine (7th ed London J & A Churchill *1958* Pp 847 45*s*)—The preface to the first edition *(1932)* of Dr G E Beaumont's textbook stated that it was meant as a short text for undergraduates and also as a help to general practitioners Psychological and dermatological medicine were purposely omitted, but otherwise it aimed to cover briefly the whole field of medicine, which it has successfully done for a long time Twenty-six years and six editions later, there has been a gigantic expansion of medical knowledge, not merely in the way of discoveries, about which the book is usually up to date and accurate, but in new ways of looking at old facts Inevitably, in the history of well-established textbooks, points are reached at which more radical revision or reconstruction is required, and perhaps, with the 8th edition ahead, this should now be considered

The Chemistry of Blood Coagulation (Springfield, *Ill* Charles C Thomas Oxford Blackwell Scientific Publications 1958 Pp 194 34*s*)—This is a translation by Dr Robert Hartmann of *Paul Morawitz*'s original work which set out the theories of blood coagulation from which our present-day ideas spring It has considerable *historic* interest and it is surprising to see that *Morawitz* was able to quote 490 references A glossary of terms used by Morawitz, with their equivalents in present nomenclature, is very helpful The translation is smooth and easy to follow

THE LANCET

LONDON 21 JUNE 1958

Agammaglobulinæmia

The discovery that extreme susceptibility to infection in some patients is related to very low levels of γ-globulin in their serum has opened a field of investigation which is being eagerly explored by physician and immunologist alike. γ-globulin may be separated into several subfractions by electrophoretic and immunological techniques. While one method may fail to reveal any at all, another may show some—presumably because they measure different subfractions Nevertheless, the term "agammaglobulinæmia" looks and sounds better than the more unwieldy "hypogammaglobulinæmia" It is already certain that there are various types of agammaglobulinæmia, and a satisfactory classification will depend on further elucidation of the physical, chemical, and immunological properties of the various subfractions Firkin and Blackburn[1] have suggested a working classification which will, no doubt, require subsequent modification.

Congenital agammaglobulinæmia was first described by Bruton[2] in a boy with recurrent bacterial infections Over 50 cases have now been reported in patients of European extraction[3-9], this disorder has not so far been recorded in Southern Europe or Latin America Nearly all the cases are in males, which suggests inheritance as a sex-linked recessive characteristic. This would not exclude an occasional case in females, but the case in a girl reported by Pearce and Perinpanayagam[10] was almost certainly of a different type because splenomegaly and lymphadenopathy, noted in their patient, have not been reported in boys Agammaglobulinæmia should be suspected when a young child has repeated bacterial infections in the absence of any other discoverable cause. The γ-globulin level of the serum in such cases varies from 0 to 25 mg per 100 ml with different methods of analysis These children have all shown an apparently normal clinical response to virus infections and to vaccination against smallpox, but virus antibodies are not found in their serum after immunisation against smallpox, poliomyelitis, or other virus antigens or after the virus infections themselves[6] Bacterial antibodies are not formed on stimulation with bacterial antigens such as T.A.B vaccine, and the Schick test remains positive after injections of diphtheria prophylactics. Isohæmagglutinins are absent or are present only in extremely low titres Plasma cells are very scanty in lymph-nodes, bone-marrow, or the inflammatory lesions themselves, this conforms with the view that these cells are the chief source of γ-globulin[11] The role of the lymphocyte is less certain, much reduction in lymphoid tissue seems to be a constant finding, but lymphopenia has not always been observed Neutropenia and eosinopenia are common[6] Good[12] reported successful skin homografts to 2 patients with congenital agammaglobulinæmia, and long survival of a skin transplant in a hypogammaglobulinæmic adult. Normally this is only possible between identical twins, because in other individuals antibody-production kills the transplants Transplants of skin from agammaglobulinæmic patients to normal persons fail, the rejection being associated with plasmocytosis in the skin and regional lymph-nodes The recurring bacterial infections in these young children usually yield rapidly to antibiotics, and they may be prevented by regular injections of γ-globulin[3] with or without protracted antibiotic prophylaxis

Primary acquired agammaglobulinæmia may be diagnosed in patients of either sex in whom recurrent bacterial infections start after early childhood, and in whom the γ-globulin level of the serum is below 100 mg per 100 ml. without other discoverable cause. The deficiency of γ-globulin tends to be less complete than in the congenital disease, immunoglobulins and isohæmagglutinins tend to be formed rather better, and there may be bacterial antibody formation to some antigens but not to most. Enlargement of the spleen and lymph-nodes is common[13-15] Several patients have been shown to have steatorrhœa, and others have presented with bronchiectasis[5 16-17] Leucopenia is common and has in some cases been relieved by splenectomy[5 14] Deficiency of plasma cells is a notable feature, as in the congenital cases[5 14] Firkin and Blackburn[1] have suggested that the acquired condition may be classified into three subgroups according to whether the lymph-nodes show (1) absence of germinal centres, (2) "benign" follicular hyperplasia, or (3) replacement of normal architecture by granulomatous tissue In fact, they have suggested that the disease may represent a mild form of reticulosis, which would make their division of acquired agammaglobulinæmia into primary and secondary forms somewhat unreal On the other hand, Citron[14] found hypergammaglobulinæmia in relatives of each sex of his 2 patients Young et al[18] recorded the same finding in the healthy mother and brother of a man with agammaglobulinæmia. This suggests that genetic factors may play a part even in the acquired form of agammaglobulinæmia

The behaviour of tuberculous infections in both the congenital and the acquired forms of primary agammaglobulinæmia contrasts strikingly with that of other bacterial infections Clinically, the acquired immune response to tuberculous infection seems to function normally in the absence of γ-globulin.[19] It might have been expected that such patients would not show delayed tuberculin hypersensitivity But one of the agammaglobulinæmic brothers described by Elphinstone et al [8] had primary intrathoracic tuberculosis with a positive Mantoux test, his disease ran a normal course, recovery being hastened by chemotherapy, his sibling reacted normally to B C G, with subsequent Mantoux conversion Parkes [19] has described the case of a woman with acquired agammaglobulinæmia who had sputum-positive pulmonary tuberculosis and a positive Mantoux test, her clinical course seemed to be no different from that of others, but she had repeated severe pyogenic infections Furthermore, delayed hypersensitivity to tuberculin has been produced in a hypogammaglobulinæmic patient by subcutaneous homograft of lymph-node from a sensitised donor [20] Immunologically tuberculosis behaves quite differently from other bacterial infections

In contrast, there is evidence that agammaglobulinæmic patients may be highly susceptible to protozoan infections In 1955 Hutchison [7] reported the first case of congenital agammaglobulinæmia in this country The pneumonia which caused the death of this patient, a boy aged 1 year and 8 months, comprised bilateral massive consolidation with a peculiar intra-alveolar acellular exudate and greatly thickened alveolar walls due to infiltration of round cells, a few polymorphs, and some macrophages, no plasma cells were recognised in the interstitial infiltrate Five years previously this child's brother had died at the age of 6 months of an identical type of pneumonia, and it seemed probable that he had had unrecognised agammaglobulinæmia Hutchison [21] subsequently reported that H S Baar had pointed out to him that the cause of the pneumonia in both siblings was infection with *Pneomocystis carinii* This protozoan infection is commonly described, under the name "interstitial plasma-cell pneumonia", in young infants in Central Europe, but it has only very rarely been described in this country No doubt the absence of plasma cells in Hutchison's cases was due to the agammaglobulinæmia Last year Bird and Thomson [9] described 2 further fatal cases of *Pneumocystis carinii* pneumonia in male infants, 1 of whom had been shown to be agammaglobulinæmic The lung sections in these cases showed appearances identical with those found in Hutchison's cases, including absence of plasma cells, and probably both infants had congenital agammaglobulinæmia *Pneumocystis carinii* infection does not respond to antibiotics Its presence should be suspected in any infant or child with an antibiotic-resistant pneumonia, and the level of the γ-globulin in his serum should be estimated

Secondary acquired agammaglobulinæmia has been described in various disorders of the reticulo-endothelial system such as myelomatosis, lymphoma, and chronic lymphatic leukæmia [1] Some but not all of these patients are unduly susceptible to bacterial infections

Transient hypogammaglobulinæmia of infancy is physiological, in that the level drops in the 1st month of life to a third of the value at birth It starts to rise again about the 3rd month, but the adult value is not reached until the age of 2 years [22] Good [12] has studied a woman with acquired agammaglobulinæmia during pregnancy In the first trimester she failed to respond to antigenic stimulation, but a significant response occurred during the last thirty days After delivery of the fœtus and placenta the immune response in the mother was no longer demonstrable The child was agammaglobulinæmic in the first 2 months of life During the 3rd month the infant began to produce γ-globulin, to make antibody, and to show plasma cells in the reticulo-endothelial tissues In some instances the low level of γ-globulin may persist longer and be associated with infections 4 fatal cases which were probably in this category were associated, not with bacterial or protozoan infections, but with vaccinia gangrenosa [23-25] The pathological findings have also differed from those in congenital agammaglobulinæmia in that although, as in the latter, lymphoid tissue is diminished with a notable reduction in germinal centres, plasma cells and monocytes may be numerous Furthermore, 1 of these patients was a female infant [23] It seems that some of the very young infants with "interstitial plasma-cell pneumonia" ascribed to *Pneumocystis carinii* in Continental reports may have had this type of hypogammaglobulinæmia

Firkin and Blackburn [1] include two other much less clearly defined categories in their classification Hypogammaglobulinæmia associated with hypoproteinæmia is most often seen in the nephrotic syndrome, but there remains an ill-defined group of patients with hypoproteinæmia and low γ-globulin level who present with episodic œdema but rarely with infections Hypogammaglobulinæmia with the familial dysproteinæmia of Homburger is characterised by familial œdema of the legs, ulcers of the legs in males, and functional vascular changes in females Dysproteinæmia may be detected only by electrophoresis and may vary from one relative to another

Local-authority Dental Services

The reports of medical officers of health and school medical officers are beginning to make their annual appearance, and almost without exception they draw attention to serious understaffing of the dental services Over the country as a whole, there are now no more local-authority dentists than there were before the war, prospects for development are definitely not bright, and there seems to be little hope of the present maternity and child-welfare and school dental services evolving to become a nation-wide comprehensive service It would be incorrect, however, to conclude that all parts of the country are suffering equally, or even to assume that, because the local-authority service in one locality happens to be well staffed, the priority classes there are necessarily much better provided with dental

care than in areas where shortage of staff exists The quality and quantity of dental attention that the children and expectant and nursing mothers of a given area receive is nowadays increasingly a function not only of the number of full-time dentists employed by the local authority but also of the number of dentists in the National Health Service who regularly treat children and the proportion of their time they are willing to reserve for the priority groups In areas where there are few local-authority dentists but relatively many private practitioners treating the priority classes, it is possible for the latter group to compensate for the deficiency in the former

The wide discrepancies in resources between one area and another cannot be justified, and a survey of the overall position seems to be the essential next step By correlating the number of local-authority dentists in each area, the number of private dentists regularly treating the priority classes under the National Health Service, and the proportion of their time devoted to this work with the size of the local population, it should be possible to identify the “ black areas ” in which facilities are inadequate Such an inquiry could be carried out for the Ministries of Education and Health, which could then try, in cooperation with the local authorities concerned, to redress the balance by stimulating recruitment of local-authority dentists into these areas, perhaps by the offer of houses and perhaps also by “ weighting ” the national salary-scale in favour of otherwise unattractive parts of the country Such a policy would probably entail the abandonment, for the time being, of national recruitment and competition between the local authorities for the services of the relatively few dentists attracted to salaried posts, in favour of an attempt to persuade those members of the profession willing to enter or already in the local-authority service to move to areas where the need for their services is greatest If successful, this measure would at least result in a more equitable distribution of limited numbers Its effects could be enhanced if, in addition, National Health Service dentists could be persuaded to devote more of their time to young children, perhaps by payment of a special bonus to practitioners in the “ black areas ” who were willing to give regular comprehensive treatment to a certain number of children each year

It seems quite unrealistic to hope to build up a comprehensive service for the priority groups on the basis of the few dentists at present attracted to appointments under the local authorities, and the most urgent problem is to ensure that those who do take such appointments go to areas where they are most needed

Annotations

INTERNIST INTO INTERNATIONALIST

LAST week in London Prof Howard Rusk of New York described how the war changed some of his ideas on what matters most in medicine He was giving the third Horder lecture, founded by the British Spas Federation, and Prof R E Tunbridge, chairman of the Federation, presided over an audience which included the Minister of Health

Before 1942 Dr Rusk was an internist in Missouri, and he came of the school of thought which sets most store by the intricacies of diagnosis Having hitherto regarded convalescence as something hardly worth bothering about, he suddenly found himself organising an Air Force rehabilitation centre He was impressed first by the appalling amount of time wasted in hospital by Service patients who ought to have been actively prepared for the quickest possible return to military duty In attempts to remedy this, various trials proved the advantages of early ambulation This was not a new discovery, for it had been recommended by a gynæcologist to his scornful colleagues of the New York Academy of Medicine in 1905 Nearly forty years after this pioneer was suppressed by the critics, “ we began to learn ”, Dr Rusk said, “ that rest in bed ought not to be used indiscriminately and could be dangerous” Merely going to bed, it was found, produced negative nitrogen and calcium balances and reduced cardiovascular efficiency

From this work his attention turned to the restoration of the men with permanent disabilities At the end of the first world war, less than 10% of the U S 400 paralysed soldiers and sailors survived to need rehabilitation, but after the second war there were 2500 of them—strong young men, with good heads and hands, who wanted to do the best they could with the rest of their lives Thanks to an active programme, parallel to the British one centred on Stoke Mandeville, 1763 of these men are now living at home and driving their own cars, and 1400 are doing some kind of work

But if this could be done for Servicemen, why should it not be done for the civilian, of whom there were some 12,500 paralysed during the same period? Why should a distinction be made between the wounded in war and the wounded at home—disabled in industry or automobile accidents? In the ten days after D-day in Normandy, the American Forces had 11,000 killed and wounded, but in the same ten days no fewer than 26,000 were killed and wounded on the highways and in the factories of their own country To give the same chances to the civilian disabled as to the soldiers, much leeway had to be made up and much work was needed of hemiplegics alone, the number in the U S A is put at 1,400,000 But what can be done by active treatment is shown by the fact that of 3000 hemiplegics (of average age 63) 88% were able, within nine months, to cope with the needs of daily life at home, and 40% were in gainful work For patients to do well, Dr Rusk found they needed three things—someone to love them, a home to go to, and a job to go to

Lord Horder, he said, was one of the first to become interested in this new yet old specialty of rehabilitation, and in his original address to the Chartered Society of Physiotherapists he had put the emphasis not on passive methods of treatment but on getting patients to do things for themselves He used stress as a therapeutic friend, and Dr Rusk, too, holds that stress, in the sense of something that forces activity, is necessary for recovery and for a happy life If the stresses of work are suddenly removed on retirement at 65, the result may be disastrous, so old people should continue to have jobs of one kind or another, though not necessarily their old ones They need above all an object, and he had seen astonishing results in a club formed for over-65s—people without anywhere to go This club has committees for everything (one committee to serve the tea and another to serve the coffee), there are bridge-drives and dances and weddings, and, while the hospital admissions of these old people for physical illness have fallen by half, their admission for senile psychosis has actually ceased This, said Dr Rusk, is real preventive medicine—the preventive medicine of the future Though he admitted that it was unscientific to say so, he believes that a purpose in life, and being happy, does something to prevent the progression of arteriosclerosis

Having just returned from an international conference called by the International Labour Office to discuss rehabilitation of the disabled workers, Dr Rusk ended his lecture by endorsing the plea of a Russian representative that against disability we should all work together He has never, he said, been anywhere in the world where doctors—regardless of race, creed, colour, politics, and curtains—do not have a common language and a common purpose In the healing arts we have a tremendous responsibility and also a tremendous opportunity In this world that is so technologically precocious and spiritually adolescent we can, if we try, build at least one block of international understanding

SMOKING AND PAPILLOMA OF THE URINARY BLADDER

IN Denmark Clemmesen et al [1] investigated the smoking habits of patients with papilloma of the urinary bladder, and they conclude that among men with this disease there is a lower proportion of non-smokers than there is among the healthy, and that, where patients smoke only *one* type of tobacco preparation, cigarettes, cigars, and cigarillos are implicated, but not pipe-smoking They noted that admission to hospitals in Copenhagen of patients with papilloma of the bladder had increased steadily from the three-year period 1944–46 up till the period 1953–55 The numbers were respectively 22 and 110 in men and 4 and 40 in women From information previously gained from the Danish Cancer Register it is stated that the increase in incidence of bladder tumours, both benign and malignant, has occurred in men but not in women and follows closely that of bronchial cancer—though this is not borne out by the hospital figures cited in their report Clemmesen et al questioned patients still alive between March, 1956, and November, 1957, about their smoking habits and compared the information thus gained with similar information from healthy persons obtained for another purpose in 1952–53 But 153 patients (more than a third) were not interviewed on account of lack of response (31) or death or inability to trace their whereabouts (122)

Lilienfeld et al [2] suggested provisionally, from a retrospective survey of clinical records of patients admitted to hospital with urinary-bladder cancer, that a significantly larger proportion of the men had smoked cigarettes for longer than had other classes of patients chosen for comparison, no such association was found in women Holsti and Ermala [3] swabbed the lips and oral cavities of mice with tobacco tar for 140 days and reported that they had observed both benign and malignant papillomatosis of the bladder at the end of a year of observation But no confirmation of this finding has been described

An association between papilloma and cancer of the bladder on the one hand and the manufacture, purification, and usage of certain aromatic amines on the other is well established in every country where such an industry exists In the future it should be possible to predict with some degree of certainty that certain chemicals are likely to be carcinogenic, but it will be far more difficult to tell which will be non-carcinogenic The risk is not confined to the aromatic intermediates from which dyes are made the finished dyes may also be carcinogenic, especially the azo compounds, and some of these, or their close chemical relatives, are in use as food dyes in some countries The exogenous causes of bladder papilloma and cancer is receiving concentrated investigation, and in this chemical age it is to be expected that the incidence will rise for reasons unconnected with tobacco smoking

THE CURE OF SOULS AND BODIES

FROM earliest times the Churches have shared with doctors the responsibility for the care of the sick, and the origins of many of our oldest hospitals show the value and strength of this ancient alliance But with the growth of scientific medicine, the partnership became uneasy The doctor was less ready to share with the priest the responsibility for his patients Today he is becoming increasingly aware of the effect of the patient on the disease and of the need to treat the person rather than the case This shift of emphasis has led many doctors to reconsider their attitude The Church of England [1] and the Church of Scotland [2] have also been considering their duties and responsibilities towards the sick in the modern world, and in the reports which Commissions of both churches have lately presented the thoughtful doctor will perhaps find a form of contract for a new and firmer partnership

Both Commissions are reserved in their attitude towards medically inexplicable healings Though they do not deny that these may occur they recognise that so-called miracles may be acclaimed in good faith by the layman who, unlike the doctor, is unaware of the normal course of a disease and possible natural remissions The Anglican Commission, which acknowledge the help they received from a committee of the British Medical Association,[3] wisely point out that many people are too ready to admire the unusual, and too slow to recognise the wonder of the familiar They regret " the popular idea that what can be scientifically explained has little or nothing to do with God " The Scottish Commission insist that " problems affecting physical and mental health require consideration *first* by a physician " and that spiritual healing should only be used with great discretion and always in consultation with the patient's doctor

The Anglican Commission suggest that the rigid separation of the spiritual and physical " which has, without doubt, enabled medicine (as much as other sciences) to make progress " has now outlived its usefulness, and both Commissions believe that the patient would now gain by closer cooperation between the churches and the doctors Doctor and priest, the Anglican Commission hold, need to respect each other's skill and understand the purpose of each other's work, and this will not be achieved by

keeping out of each other's way Consultation over individual patients is the easiest and most natural way to draw priest and doctor together, but both Commissions suggest that this could be extended by meetings between small groups of clergy and doctors to exchange views and experiences They also propose that medical and theological students should be given an opportunity of learning something of the work and responsibilities of each other's profession The Scottish Commission was able to report that in at least one of their theological colleges a course of lectures is given to final-year students by the medical superintendent of a mental hospital and that the students visit the wards of the hospital Another opportunity for cooperation which the Scottish Commission urge is in hospitals with chaplains They would like to see the chaplain treated as a recognised member of the staff and drawn more often into consultation with his medical colleagues

In their training and approach the doctor and the priest inevitably differ But they share a common concern for the patient, and when a patient seeks help from both it will be most effectively given by colleagues who respect and trust each other

ANTICHOLINESTERASE INHIBITORS

THE anticholinesterases commonly used in the diagnosis and treatment of myasthenia gravis are neostigmine, pyridostigmine, and edrophonium Less commonly used are organophosphorous compounds with powerful anticholinesterase activity—di-isopropyl fluorophosphate and tetraethyl pyrophosphate Overdosage of an anticholinesterase may lead to a " cholinergic crisis " due to accumulation of acetylcholine in the tissues This stage is often difficult to recognise Clinical deterioration after an intravenous dose of edrophonium is evidence of the cholinergic state, and, because of the drug's transient action, this test is fairly safe Until recently there was no specific therapy for anticholinesterase poisoning The main weapons were withdrawal of neostigmine and administration of atropine, which neutralises the gastrointestinal, bronchial, and cardiac effects A free airway must be maintained, and sometimes mechanical aids to respiration are necessary *d*-Tubocurarine has been recommended[1], but the dose needed for " competitive blocking " of anticholinesterase is uncomfortably close to that producing muscular paralysis The action in man of two specific anticholinesterase inhibitors has now been thoroughly studied by Grob and Johns[2]

These substances are pyridine-2-aldoxime (2-P.A M) and diacetyl monoxime (D.A M) They were found to reverse cholinesterase inhibition and neuromuscular block due to organophosphorous or quaternary ammonium anticholinesterases 2-P A M proved the better of the two when administered before or after other anticholinesterases A very large dose of 2-P A M can produce a neuromuscular block in animals, but in man the recommended dose—1–2 g intravenously—is unlikely to have this effect Clearly 2-P A M should now be held ready for emergency therapy in cholinergic crises Unfortunately at this serious stage many myasthenics are in a precarious balance between the progressive disease and high neostigmine dosage, thus, whatever treatment is applied, many may fail to recover Namba and Hiraki[3] found that these two substances also counteracted ' Parathion ', an organophosphorous insecticide which sometimes gives rise to accidental poisoning

A NEW HOSPITAL REGION

THE South West Metropolitan Regional Hospital Board, responsible for a vast straggling area and a population of nearly 5 million, has deliberately fostered partial autonomy in its most distant sector—that of Wessex (Hampshire, Dorset, Wiltshire, and the Isle of Wight) The Minister of Health has now announced that the autonomy is to be complete from April 1 next year, when a Wessex Regional Hospital Board will come into operation The new region, which is compact, contains about 1³/₄ million people, and in it every specialty except neurosurgery is already covered If Southampton were eventually to have a medical school, this might end the region's reliance on London, but meanwhile it is likely to continue its association with the University of London—notably the British Postgraduate Medical Federation and the three undergraduate teaching hospitals (St George's, St Thomas's, and Westminster) that are linked with the South West Metropolitan region

Ten years ago a Wessex hospital region would have had to rely on London for many specialties Today that is no longer so The fact that the new region will from the start be so largely self-reliant testifies to the remarkable improvement, during the past decade, in hospital services outside the capital

ANTIBODY FORMATION IN VITRO

THE mechanism by which antibodies are formed is not completely understood, but it has been found that lymph-nodes transplanted from an immunised animal to a normal animal continue to produce antibody in the new host Washed cells from the lymph-nodes of an immunised rabbit give rise to antibodies when injected intravenously into a normal rabbit[1] Antibody formation also occurs in vitro in cultures of various tissues removed from immunised animals[2,3] Some interesting experiments which carry the matter a stage further are now reported[4] by Dr Nossal and Professor Lederberg, well known for his work on bacterial genetics in the University of Wisconsin, who has been the Fulbright visiting professor in Melbourne

Rats were each immunised with two different strains of salmonella and the popliteal lymph-nodes were excised Cell suspensions were prepared from these lymph-nodes, and by micromanipulation methods single cells were isolated Some of these single cells when incubated in a serum-saline medium produced antiflagellar antibodies capable of immobilising one or other of the bacterial strains with which the rats had been immunised

Quite apart from the interesting possibility of demonstrating antibody formation in vitro by single cells, this achievement makes it possible to investigate various problems of antibody formation The two salmonella strains used had different specific flagellar antigens, and the rats produced two distinct antibodies each capable of immobilising the specific strain The question arises therefore whether the two kinds of antibody are produced by a single cell or whether a separate cell is necessary to produce each kind of antibody In the experiments reported, 456 single cells were tested for antibody production, and of these 33 were active against *Salmonella adelaide* and 29 against *Salmonella typhi*, but none of these 62 immobilised both strains Possibly some cells may have

produced a very small amount of the second antibody in addition to the predominantly large amount of the main antibody, but the conclusion seems valid that "when an animal is stimulated with two contrasting antigens, individual cells tend to form one species of antibody" There remains the problem of why this is so Is it an interference phenomenon, and can a cell deal with only a single antigen at a time? Or is a cell genetically restricted to the kind of antigen to which it can form antibodies? In order to answer such questions it may be necessary to go back to a previous stage in the process—that of the initial stimulus to antibody formation

ARTIFICIAL RESPIRATION

It has been proposed that an old method for artificial respiration, and a variant of it, should be used for emergency resuscitation Safar et al [1] maintain that, used properly, mouth-to-mouth insufflation is far better than any of the push-pull methods certainly the figures given for the ventilation achieved suggest that their technique is efficient They criticise the method originally used for testing and comparing the different manual methods of artificial respiration They point out that in all instances the patients, though anæsthetised and curarised, were also intubated, thus ensuring a clear airway When they tested methods such as the arm-lift/back pressure (Holger-Nielsen) on patients who were not intubated the volume per respiration was low—not much above that which would wash out the dead space Without intubation, and even in the prone position, the toneless soft palate and pharynx partly block the airway and severely limit possible ventilation Even with intubation Safar et al did not succeed in moving more than 700–260 c cm of air with either the Holger-Nielsen or the Silvester method This is far below the ventilation regularly attained in the investigation of Gordon et al,[2] but the reason for this difference is not clear

Safar et al tested the mouth-to-mouth method with the subject on a hard table and on the floor They point out that one advantage of the method is that the operator has both hands free to hold the lower jaw forward and to keep the mouth open, thus ensuring a clear airway, at the same time the hands can be used to close the patient's nostrils The operator places his own mouth well over that of the patient and, at first vigorously, and later less vigorously, blows out his own expired air until the patient's chest expands The operator then removes his mouth and allows expiration to occur naturally by elastic recoil It is claimed that this method can be used by anyone on anyone, that it can be maintained for long periods without fatigue or dizziness, that it easily achieves a ventilation of 1000–1500 c cm at 12–20 respirations a minute, and finally that it is easily taught and learnt Occasionally air may enter the patient's stomach, but it can be removed by compression of the abdomen, and it does not interfere with the respiratory process The main objection to the mouth-to-mouth method is æsthetic, and to overcome this Safar et al have designed a simple S-shaped tube which can rapidly be inserted down to the pharynx, the operator can then expire through the outer end of this tube, giving oropharyngeal respiration The ventilation by using the tube is just as good as in the direct mouth-to-mouth method Insertion of the tube is said to be easy, to be soon learnt, and to involve negligible delay in starting resuscitation Further, the tube is small and light and can easily be carried in the pocket Mouth-to-mouth resuscitation can be used on patients of all ages, but Safar et al emphasise that for infants the operator must not expire vigorously lest he rupture alveoli, little more than an expiratory puff is required

Safar et al state that they tried the Holger-Nielsen method after inserting their pharyngeal tube and found that ventilation was extremely poor unless the lower jaw was held forward—obviously an impossible manœuvre for a rescuer working single-handed It is difficult to reconcile this and some other criticisms of the Holger-Nielsen and Silvester methods with the successes known to have followed their use,[3] and even that of the far less efficient Schäfer method It is also difficult to see how dizziness is avoided if the operator is hyperventilating sufficiently to supply "virtually room air" to the patient If the operator does not hyperventilate the method is open to objection by those who believe that 4–5% CO_2 should not be supplied to one who is anoxic and probably hypercapnic Nevertheless, though most people cannot be expected always to carry an oropharyngeal tube and must therefore stick to the Silvester or Holger-Nielsen methods, all workers who are likely to be faced by emergencies might well learn and test this simple method, and, if they find it good, use it All the speakers in an American Symposium on this method[4] spoke favourably of it Certainly no unreasonable conservatism should be allowed to prevent progress in saving life or preventing that death in life—the decerebrate state resulting from anoxia

BIRTHDAY HONOURS

The award of the Order of Merit to Sir Macfarlane Burnet, the distinguished virologist and immunologist, will be widely and warmly welcomed Burnet graduated in medicine in the University of Melbourne, where he is now director of the Walter and Eliza Hall Institute of Medical Research, and he devoted two periods to study and research in this country, in 1926–27 at the Lister Institute and in 1932–33 at the National Institute for Medical Research at Hampstead But he has spent most of his life, in biological and medical research of one kind or another, in Melbourne, where he has built a school which attracts workers from all over the world He has done much fundamental work on bacteriophages, and recently he has made equally detailed researches into the influenza viruses, and their methods of penetrating cells and multiplying therein In these two fields he has profoundly influenced scientific thought He is probably better known, however, for his ability to generalise in matters of wide biological significance

Doctors in the Dominions figure prominently elsewhere in the Honours List Thus Dr C R Burns and Prof F H Smirk, of New Zealand, are appointed K B E, and Prof J C Eccles, Mr B T Edye, and Brigadier K B Fraser, of Australia, and Colonel A G Curphey, of Jamaica, are created knights Of the honours to doctors in this country, the appointment of Mr J D McLaggan as K C V O and the knighthood conferred on Brigadier J S K Boyd and Mr E W Riches will give special pleasure to many We congratulate these and the others named in the list on p 1332

Sir Arnold Stott, consulting physician to the Westminster Hospital, died at his home in Surrey on June 15 at the age of 72

Public Health

OUTBREAK OF POLIOMYELITIS IN A SMALL URBAN COMMUNITY

R D PEARCE
M.R.C S , D.P H
MEDICAL OFFICER OF HEALTH TO THE URBAN DISTRICTS OF BRIGHTLINGSEA, CLACTON, AND FRINTON AND WALTON, AND THE RURAL DISTRICT OF TENDRING, ASSISTANT COUNTY MEDICAL OFFICER

POLIOMYELITIS broke out in Brightlingsea (population about 4500) in the spring of 1957, 46 cases being notified in seventeen weeks, and 40 of these being subsequently confirmed clinically (table I)

Brightlingsea, an east-coast yachting centre, is situated on the eastern side of the Colne estuary in East Essex The two main industries are the building of small ships and boats and the oyster fisheries

Originally the town was probably an island Today it is served by one road three miles long, which connects Brightlingsea with the Colchester–Clacton Road, B1027 A single railway line connects the town with the main Clacton line The surrounding countryside is agricultural, and therefore a small urban community exists Most of the inhabitants work in the town, but an increasing number work in a large town about nine miles distant The accompanying map shows the relations of Brightlingsea

TABLE I—AGE-GROUPS AFFECTED

Age (yr)	Paralytic		Non-paralytic	
	Male	Female	Male	Female
1-2	1	1		1
3	2	1	1	2
4	3		2	2
5-9	8	4	2	1
10-14				2
15-24	1			1
25 or more	2	1		2
Total	17	7	5	11

So far as it is possible to ascertain, there had never been a notified case of poliomyelitis in Brightlingsea until the autumn of 1952, when 2 patients with paralytic poliomyelitis were admitted to hospital In the autumn of 1954 8 patients with non-paralytic and 6 with paralytic poliomyelitis were admitted to hospital In October, 1955, 6 cases of non-paralytic poliomyelitis were notified, and from the records it appears that none of these patients was admitted to hospital At that time, however, there were several cases of aseptic meningitis in the surrounding districts, therefore, although the diagnosis of these 6 cases must remain in doubt, it is likely that they were cases, not of poliomyelitis, but of aseptic meningitis In January, 1956, a girl, aged 18, who worked out of Brightlingsea contracted paralytic poliomyelitis No other cases were notified during the year

At the end of January, 1957, a boy, aged $4^1/_2$ years, with symptoms suggesting poliomyelitis, was seen by his general practitioner and was subsequently admitted to hospital and diagnosed as having paralytic poliomyelitis No other case of poliomyelitis was known to exist at that time in East Essex The boy's father worked as a porter on a main-line station Neither the boy's father nor his mother had any illness The boy was discharged from hospital on March 14, 1957 On March 16 2 more cases of poliomyelitis were notified, and from then until the beginning of June there were 37 further confirmed cases

The Brightlingsea epidemic was the first phase of a widespread outbreak of poliomyelitis which later extended north-west to Colchester and the surrounding villages Some centres of population to the east had very few cases, and one centre escaped the epidemic entirely The average incidence in the areas affected was rather more than 1 case per 1000 population—much lower than the 1% incidence in Brightlingsea

Investigations

All the patients were admitted to the infectious-disease unit of the Colchester Group Hospitals Lumbar puncture was done on nearly all the patients, and stools and samples of blood were taken and sent for examination to Dr P Martin at the Public Health Laboratory, Ipswich Samples of stool from some of the contacts were also submitted for isolation of virus Each family in which a case of poliomyelitis had occurred was visited, and a careful history was taken Serological investigations were made at the Virus Reference Laboratory, Colindale, and the results of these investigations are reported in an accompanying article (Boissard 1958)

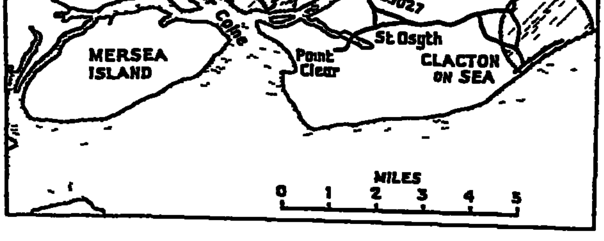
Clinical Findings

Nearly all the Brightlingsea patients complained of frontal headache. They had pyrexia (99–103°F), slight stiffness of the neck, and fairly severe stiffness of the lower two-thirds of the back. In about half the cases the hamstrings felt tight Of the 40 patients 28 had a definite history of an "invasion" stage, with pyrexia, headache, and coryza, before the onset of meningeal symptoms and signs The interval between this "invasion" stage and the onset of meningism varied from a few hours to several days

24 cases were paralytic, most of them showing only slight or moderate muscle weakness Only 3 patients needed subsequent treatment as inpatients of an orthopædic hospital This is partly attributable to the mildness of many cases, but is also due to the fact that a particularly good physiotherapy service exists in the infectious-disease unit to which they were originally admitted

Isolation of Virus

When this outbreak began, it was fortunate that I had been discussing with Dr Martin, director of Ipswich Public Health Laboratory, the possibility of isolating the virus from the fæces of persons with poliomyelitis Subsequently, with his cooperation, Dr P J Wormald,



Topographical relations of Brightlingsea.

of the Cambridge Public Health Laboratory, isolated type-1 virus from 13 of the cases in this outbreak No virus was isolated from the stools of the 6 contacts which were submitted for examination

Spread of Poliomyelitis

An impressive fact at the start of the outbreak was the apparent association of some of the patients (table II) Cases 2, 4, 5, and 6 all lived within a short distance of each other and played together out of school Case 3 had associated with case 2 at school, and case 9 was the mother of case 3 No evidence was obtained of spread of the disease by food or by water, the spread seemed to be either by droplet infection or by fæces The "narrow stream" spread of poliomyelitis seemed to continue throughout the outbreak

The following probable chains of spread are interesting

Chain A —Case 4 (onset March 17) probably infected case 6 (onset March 22) They played together out of school but attended different schools Case 13 (onset March 31) played regularly with cases 4 and 6 Case 30 (onset April 14) was the father of case 13, and case 35 (onset April 19) was the married sister of case 30 and was alleged to have been in contact with cases 13 and 30 Case 20 (onset April 5) also played with case 6, who lives opposite Case 23 (onset April 7) was the sister of case 4 (onset March 17) and had been kept in home and garden quarantine since her sister's illness Case 14 (onset April 1) had been in contact with case 4 at school

It is possible to lengthen chain A Case 2 (onset March 11) was the neighbour and playmate of case 4 Complement fixation tests indicated that case 2 had type-1 poliomyelitis Case 5 (onset March 18) was the father of case 2 The complement-fixation tests again indicated a type-1 infection, but type-2 virus was isolated from the stools It is for this latter reason that these 2 cases are not included in chain A

Chain B —Case 12 (onset March 31) played regularly with case 19 (onset April 4) Case 19 was isolated from March 31 Case 22 (onset April 7) was the aunt of case 12 and was in contact with him on March 24 and 31

In 1956 I vaccinated 13 children in Brightlingsea against poliomyelitis None of these children had symptoms of poliomyelitis, although several of them were very close contacts of confirmed cases of poliomyelitis Furthermore, in each of nine families concerned there were 2 cases of clinical poliomyelitis

Incubation Period

The communicability of poliomyelitis appears to be greatest during the latter part of the incubation period and the onset of symptoms An attempt was made to calculate the probable shortest incubation period in some of the cases For the purpose of this calculation the onset of the invasion phase of the illness was taken as the onset

TABLE II—ANALYSIS OF CASES

Case no	Age (yr)	Sex	Type of poliomyelitis	Onset (1957)	Admission to hospital (1957)	Shortest possible incubation (days)	Remarks
1	4	M	Paralytic	Jan 28	Feb 5		No contact established
2	6	M	„	March 11	March 11		No contact established, attended infants' school, C F T suggested type-1 virus
3	6	M	„	„ 15	„ 15		Attended same school as cases 2 and 4, C F T suggested type-1 virus
4	7	F	„	„ 17	„ 19		Attended same school as cases 2 and 3, neighbour and close contact of case 2
5	33	M	„	„ 18	„ 19	7	Father of case 2, type-2 virus isolated from stools, C F T suggested type-1 virus
6	9	F	„	„ 22	„ 26	6	Contact of case 4 regularly until March 16, type-1 virus isolated from stool
7	$3^{10}/_{12}$	M	„	„ 25	April 1		No known contact, type-1 virus isolated from stool
8	3	F	Non-paralytic	„ 25	„ 2		Close companion of case 7, probably infected from same unknown source, type-1 virus isolated from stool
9	29	F	Paralytic	„ 27	„ 6	12	Contact (mother) of case 3
10	20	M	„	„ 28	March 28		No established contact, cubmaster and Sunday school teacher
11	5	F	„	„ 31	„ 31		No known contact, attended Sunday-school, attended infants' school until March 22, kept away by mother as precautionary measure only, type-1 virus isolated from stools
12	3	M	„	„ 31	April 3		No known contact
13	$6^{10}/_{12}$	M	„	„ 31	„ 8		Played with cases 4 and 6, attended school for four days after start of invasion period April 5–8, type-1 virus isolated from stools
14	6	M	„	April 1	„ 1		Attended infants' school, had played with case 4 at school, type I virus isolated from stool
15	4	M	Non-paralytic	„ 1	„ 3		Had played a week previously with child X, who had been ill with vague pyrexial illness
16	$4^{1}/_{2}$	M	Paralytic	„ 2	„ 3		Contact of case 15 and X
17	$4^{1}/_{2}$	F	Non-paralytic	„ 2	„ 3		No definite contact
18	6	F	„	„ 4	„ 8		Attended infants' school until April 4, contact of case 3 in school twenty days before and of X fourteen days before
19	4	M	Paralytic	„ 4	„ 8	5	Played regularly with case 12 until March 30, no contact with other children whatever
20	$8^{1}/_{2}$	M	„	„ 5	„ 6	14	Played with case 6, who lived opposite, until March 22, attended junior school, type-1 virus isolated from stool
21	3	M	Non-paralytic	„ 6	„ 8		Indefinite contact of case 12, type-1 virus isolated from stool
22	33	F	„	„ 7	„ 7	7	Aunt of case 12, had been in contact seven and fourteen days before onset
23	13	F	„	„ 7	„ 11	18	Sister and contact of case 4, had been isolated at home and in garden since March 17 (onset of case 4)
24	7	F	Paralytic	„ 7	„ 13		Attended infants school, in contact with X and in contact with case 18 before March 29
25	4	M	Non-paralytic	„ 7	„ 14		Contact and neighbour of case 21, type-1 virus isolated from stool
26	$^{10}/_{12}$	F	„	„ 7	„ 14		Sister of case 25 and contact of case 21, type-1 virus isolated from stool
27	3	F	Paralytic	„ 8	„ 8	15	Played each day with case 8, most likely contact, last played on March 24
28	4	F	Non-paraltyic	„ 10	„ 13		Sister of case 24, type-1 virus isolated from stool
29	3	F	„	„ 14	„ 17		No known contact
30	36	M	Paralytic	„ 14	„ 18	14	Father of case 13
31	9	M	„	„ 14	„ 21	10	Regular playmate of case 18 and her brother (case 33), type-1 virus isolated from stool
32	$16^{3}/_{4}$	F	Non paralytic	„ 15	„ 15		Teacher at Sunday school, no other contact
33	9	M	Paralytic	„ 15	„ 15	7	In regular contact with case 18 (sister) until April 8, type-1 virus isolated from stool
34	$^{11}/_{12}$	M	„	„ 18	„ 22	4	Brother of case 31, no other contact known
35	42	F	Non-paralytic	„ 19	„ 20		Sister of case 30 and aunt of case 13, in contact regularly with each
36	6	M	„	„ 22	„ 22		Neighbour and contact of case 24 and playmate of case 33, attended infants' school
37	5	M	„	„ 23	„ 23		No known contact, had been kept away from infants' school for three weeks before April 9, unknown illness in children next door
38	$^{11}/_{12}$	F	Paralytic	„ 26	„ 29		Sister of case 37
39	12	F	Non-paralytic	May 4	May 9	11	Last attended secondary school on April 9, neighbour and playmate of case 37
40	5	M	Paralytic	June 4	June 4		Father a schoolmaster, no contact known

ing (N) antibody Case 13, from whom type-1 poliovirus was isolated in the Cambridge Public Health Laboratory, had paralytic poliomyelitis, but his sister (case 18) and the 4 other children with type-1 N antibody were not known to have had poliomyelitis Table II shows that 5 of the 6 sera with type-1 N antibody also fixed complement with type-1 virus

Type-2 antibody—Only case 17's serum (table I) neutralised the test dose of type-2 virus at 1/32 dilution None of these sera fixed complement with type-2 virus at 1/4 dilution (table II)

TABLE II—RECIPROCALS OF COMPLEMENT-FIXING ANTIBODIES TO THREE POLIOMYELITIS VIRUSES

Vaccinated children				Unvaccinated children			
Case no	Poliomyelitis virus			Case no	Poliomyelitis virus		
	Type 1	Type 2	Type 3		Type 1	Type 2	Type 3
1	<4	<4	<4	10	<4	<4	<4
2	>64	16	64	11	>16<32	<4	>4<8
3	<4	<4	>8<16	12	16	<4	<4
4	>4<8	<4	<4	13	>8<16	<4	<4
5	8	<4	<4	14	<4	<4	<4
6	>16<32	4	>32<64	15	<4	<4	<4
7	>16<32	>4<8	8	16	16	<4	<4
8	32	16	<4	17	<4	<4	<4
9	>16<32	4	>8<16	18	32	<4	<4

Type-3 antibody—No serum neutralised the test dose of type-3 virus at the lowest dilution tested, but table II shows that case 11's serum contained heterologous C F antibody to type-3 virus

These serological results indicate that infection by type-2 and type-3 viruses had not been hitherto widespread in this community

Sera of Vaccinated Children

Type-1 antibody—Table I shows that cases 1 and 3 had serum N antibody commensurate with the level of type-1 antibody found a year after two doses of vaccine (Medical Research Council 1957b) These two sera did not fix complement with type-1 virus (table II), and the findings suggest that these 2 children escaped infection during the epidemic The type-1 N antibody titres of the 7 other sera were higher than might be expected a year after immunisation, and it appears probable that antibody response had been reinforced in these children by infection with type-1 virus In 4 of these sera the high titres found would be unusual after a primary infection in unimmunised children These 7 sera reacted positively in the C F T (table II), but the C F antibody titre was low in the sera of cases 4 and 5 (see below)

Type-2 antibody—Case 8's serum N antibody titre (table I) of 1/8192 suggests an infection by type-2 virus either before or after immunisation Table II shows that 5 of the 9 sera fixed complement with type-2 virus, a rational explanation being that this was because of heterologous C F antibody produced in response to infection of these children by type-1 virus (Casals et al 1952, Svedmyr et al 1953, Schmidt and Lennette 1956) The lack of heterologous C F antibody in the sera of cases 4 and 5 is discussed below

Type-3 antibody—Sera from cases 5 and 8 did not neutralise the test dose of type-3 virus at 1/8 dilution, and at 1/2 dilution when subsequently retested Case 6's serum N antibody was of the order of a secondary response, irrespective of whether primary immunisation or infection occurred first In case 3's serum (table I) type-1 and type-2 N antibodies were within the range of titres found a year after two doses of vaccine, but her serum type-3 N antibody was at the uppermost limit of the observed range (Medical Research Council 1957b) Since this serum gave fixation with type-3 virus in the C F T, there is reasonable evidence that case 3 had been infected by this virus, possibly within the preceding year It is known that type-3 virus was introduced into the area during the epidemic (J A Dudgeon, personal communication) Of the 5 sera which gave heterologous C F reactions with type-2 virus 4 gave heterologous C F reactions with type-3 virus (table II) The fact that case 8's serum did not react in this way with type-3 virus, although fixing complement with type-2 virus, is similar to the observation of Svedmyr et al (1953) that convalescent sera may fix complement with sometimes one and sometimes both of the heterologous viruses The sera of cases 4 and 5 showed no heterologous C F antibody to type-3 virus

Discussion

There were striking similarities and differences in both N and C F antibodies in the sera of these two small groups of children differing only, so far as could be ascertained, in their vaccination status Both groups showed serological evidence of infection by type-1 poliovirus—7 of the vaccinated children against 6 of the unvaccinated children—yet all but one of these infections were subclinical

It is clear that, in some of the vaccinated children, natural infection had had a similar effect on N antibody to that of a third or reinforcing dose of poliomyelitis vaccine In contrast to the unvaccinated children, most of the vaccinated children's sera had all three types of N antibody in high titre a year after they had received two doses of poliomyelitis vaccine

Since these sera were collected four months after the April peak of the epidemic, no evidence can be adduced about transitory heterotypic type-2 antibody (Casals et al 1952, Sabin 1952)

The culture-medium control, which is known to fix complement with very few human sera in the absence of any anticomplementary effect, gave no indication that non-specific C F reactions occurred between the test sera and monkey-kidney cell antigens or other constituents

Table II shows that there were more monotypic C F reactions in the sera of the unvaccinated children than in the sera of the immunised group Since the two groups of children were of similar age, this difference in serological response must be ascribed to immunisation with poliomyelitis vaccine This immunotherapy presumably had caused heterologous C F antibody to appear in the sera of those children who had experienced either an earlier or a subsequent subclinical poliovirus infection Black and Melnick (1954) noted a similar phenomenon in a group of 30 persons tested for N and C F antibodies before and after inoculation with a formalin-inactivated type-1 virus None had C F antibodies before inoculation The C F response was confined almost entirely to those persons and those types where there was pre-existing N antibody

Case 11's serum contained heterologous C F antibody to type-3 virus in the absence of N antibody at 1/8 dilution of serum Similar observations were made by Melnick (1955) and Hammon et al (1955) Attention was directed by Mayer (1955) to possible reasons for cross-C F reactions

Laboratory, for their cooperation, and *Mr James Colvin*, the surveyor and public health inspector of Brightlingsea, who assisted me so ably in these investigations during the outbreak

ANTIBODIES AGAINST POLIOVIRUS IN VACCINATED AND UNVACCINATED CHILDREN IN AN EPIDEMIC AREA

G P B Boissard
M B Lond, Dip Bact
From the Virus Reference Laboratory, Central Public Health Laboratory, Colindale, London, N W 9

An epidemic caused by type-1 poliovirus broke out in Brightlingsea, Essex, in the first half of 1957 (Pearce 1958) In a population of 4500 there were notified 46 cases, of which 40 were later confirmed as poliomyelitis

13 children in Brightlingsea had each received two doses of poliomyelitis vaccine on May 17 and June 13, 1956 The high clinical attack-rate in Brightlingsea in April, 1957, prompted a comparative antibody study of small groups of vaccinated and unvaccinated children A single sample of blood was obtained from each child on July 4, 1957 Except for 1 unvaccinated child, both groups consisted of children who had not been ill It was of particular interest to determine, if possible, whether infection with poliomyelitis virus after immunisation would cause heterologous complement-fixing (C F) antibodies to appear The children were selected as follows

The names of unvaccinated children, aged 3–9 years, on the birth registry in Brightlingsea were arranged in alphabetical order and numbered 1–138 60 of these, consisting of 26 boys and 34 girls, were similar in age to the vaccinated group, and 12 of them were paired with 12 of the vaccinated children according to sex by using random numbers Of the 9 vaccinated and 9 unvaccinated children allowed to take part 6 pairs turned out to have been randomised for age and sex as described, since 3 unvaccinated half-pairs who defaulted were replaced by 3 unvaccinated children who were not randomised alternatives for those particular vaccinated children

Methods

Tissue cultures for neutralisation tests—Six-day cultures of monkey-kidney cells were maintained on 1 ml of Eagle's (1955) medium, with added 2 0% of inhibitor-free inactivated horse-serum and 0 1% sodium bicarbonate The inoculum used for each culture in titrations was 0 1 ml of virus or of virus-serum mixture All the test-serum, control-serum, and control-virus titrations were done on one batch of tissue cultures Fluid from cultures showing degeneration of doubtful origin was subinoculated on the sixth day after inoculation This was done in 29 of 742 of the cultures used (3 9%)

Virus suspensions—The strains used in neutralisation (N) and in complement-fixation tests (C F T) were type-1 Mahoney, type-2 MEF-1, and type-3 Saukett These were grown in monolayer cultures of monkey-kidney cells maintained on Mixture 199 (Morgan et al 1950) The harvested culture fluids were centrifuged at 5000 r p m for an hour at +4°C, and the pooled supernatant fluid of each type was distributed and stored at this temperature

Virus titrations—Suspensions were diluted in tenfold steps with Mixture 199 containing 0 1% bicarbonate Four tissue cultures were inoculated with each dilution of virus Geometric mean titres were $10^{-6\,0}$, $10^{-5\,7}$, and $10^{-6\,3}$ for virus of types 1, 2, and 3 respectively

Neutralisation by test sera—These were stored at −30°C and were thawed once only before being tested Sera were heated at 60°C for twenty minutes Serial dilutions of each serum in Hanks' solution containing 0 01% sodium bicarbonate were mixed in 0 6 ml volumes with an equal volume of virus suspension to give serum dilutions of 1/8–1/4096 in fourfold steps and an estimated challenge dose of 100 TCID_{50} per 0 1 ml of inoculum of each virus type After being shaken the serum-virus mixtures were placed at 37°C in an air incubator for three and a half hours (Medical Research Council 1957a) before inoculation of two tissue cultures with each dilution

Neutralisation by control sera—British Standard poliomyelitis monkey antisera from the department of biological standards, Mill Hill, were hydrated as directed Serial dilutions of each serum were mixed in 1 ml volumes with an equal volume of each virus suspension used in the test, to give control serum dilutions from 1/40 to 1/320 in twofold steps These were then treated like the test sera, except that four tissue cultures were inoculated with each dilution

Complement-fixation test—The method of Fulton and Dumbell (1949) was used in straight-line tests as described by Le Bouvier (1953) The optimum concentrations of the live virus suspensions which served as antigens in the test were 1/2 for Mahoney and Saukett, MEF-1 was used as the undiluted suspension Two exact units of complement were added in the test, the unit being defined as the highest dilution of complement which, when titrated in the presence of each virus suspension under the conditions of the test, caused 50% hæmolysis of the maximally sensitised sheep red cells Serum dilutions in barbitone buffer were screened at initial dilutions of 1/4–1/64 in twofold steps Serum controls, virus and culture-medium controls, and hæmolysis controls were included in the test

Results

Control Sera

The neutralising titres obtained in the test were 1/160, 1/190, and 1/280 for type 1, 2, and 3 sera respectively The geometric mean titres for the British Standard poliomyelitis sera are published as 1/480, 1/806, and 1/960 for type 1, 2, and 3 sera respectively (Medical Research Council 1957a), but in the M R C tests five times greater volumes of each serum were used In table I the reciprocals of the neutralising antibody titres of the test sera have been multiplied by the ratios 3, 4, and 3¹/₂ for types 1, 2, and 3 respectively, to facilitate comparison of these results with those published by the Medical Research Council (1957b) on the antigenic activity of British poliomyelitis vaccine in children

Sera of Unvaccinated Children

Type-1 antibody—Table I shows that of the 9 sera, 6 had type-1, 1 had type-2, and none had type-3 neutralis-

Type-3 antibody—No serum neutralised the test dose of type-3 virus at the lowest dilution tested, but table II shows that case 11's serum contained heterologous C F antibody to type-3 virus

These serological results indicate that infection by type-2 and type-3 viruses had not been hitherto widespread in this community

Sera of Vaccinated Children

Type-1 antibody—Table I shows that cases 1 and 3 had serum N antibody commensurate with the level of type-1 antibody found a year after two doses of vaccine (Medical Research Council 1957b) These two sera did not fix complement with type-1 virus (table II), and the findings suggest that these 2 children escaped infection during the epidemic. The type-1 N antibody titres of the 7 other sera were higher than might be expected a year after immunisation, and it appears probable that antibody response had been reinforced in these children by infection with type-1 virus In 4 of these sera the high titres found would be unusual after a primary infection in unimmunised children These 7 sera reacted positively in the C.F T (table II), but the C.F antibody titre was low in the sera of cases 4 and 5 (see below)

Type-2 antibody—Case 8's serum N antibody titre (table I) of 1/8192 suggests an infection by type-2 virus either before or after immunisation Table II shows that 5 of the 9 sera fixed complement with type-2 virus, a rational explanation being that this was because of heterologous C F antibody produced in response to infection of these children by type-1 virus (Casals et al. 1952, Svedmyr et al 1953, Schmidt and Lennette 1956) The lack of heterologous C F antibody in the sera of cases 4 and 5 is discussed below

Type-3 antibody—Sera from cases 5 and 8 did not neutralise the test dose of type-3 virus at 1/8 dilution, and at 1/2 dilution when subsequently retested Case 6's serum N antibody was of the order of a secondary response, irrespective of whether primary immunisation or infection occurred first In case 3's serum (table I) type-1 and type-2 N antibodies were within the range of titres found a year after two doses of vaccine, but her serum type-3 N antibody was at the uppermost limit of the observed range (Medical Research Council 1957b) Since this serum gave fixation with type-3 virus in the C F T, there is reasonable evidence that case 3 had been infected by this virus, possibly within the preceding year It is known that type-3 virus was introduced into the area during the epidemic (J A Dudgeon, personal communication) Of the 5 sera which gave heterologous C F reactions with type-2 virus 4 gave heterologous C.F reactions with type-3 virus (table II) The fact that case 8's serum did not react in this way with type-3 virus, although fixing complement with type-2 virus, is similar to the observation of Svedmyr et al (1953) that convalescent sera may fix complement with sometimes one and sometimes both of the heterologous viruses The sera of cases 4 and 5 showed no heterologous C F antibody to type-3 virus

Discussion

There were striking similarities and differences in both N and C F antibodies in the sera of these two small groups of children differing only, so far as could be ascertained, in their vaccination status Both groups showed serological evidence of infection by type-1 poliovirus—7 of the vaccinated children against 6 of the unvaccinated children—yet all but one of these infections were subclinical

It is clear that, in some of the vaccinated children, natural infection had had a similar effect on N antibody to that of a third or reinforcing dose of poliomyelitis vaccine In contrast to the unvaccinated children, most of the vaccinated children's sera had all three types of N antibody in high titre a year after they had received two doses of poliomyelitis vaccine

Since these sera were collected four months after the April peak of the epidemic, no evidence can be adduced about transitory heterotypic type-2 antibody (Casals et al 1952, Sabin 1952)

The culture-medium control, which is known to fix complement with very few human sera in the absence of any anticomplementary effect, gave no indication that non-specific C F reactions occurred between the test sera and monkey-kidney cell antigens or other constituents

Table II shows that there were more monotypic C.F reactions in the sera of the unvaccinated children than in the sera of the immunised group Since the two groups of children were of similar age, this difference in serological response must be ascribed to immunisation with poliomyelitis vaccine This immunotherapy presumably had caused heterologous C F antibody to appear in the sera of those children who had experienced either an earlier or a subsequent subclinical poliovirus infection Black and Melnick (1954) noted a similar phenomenon in a group of 30 persons tested for N and C.F antibodies before and after inoculation with a formalin-inactivated type-1 virus None had C F antibodies before inoculation The C.F response was confined almost entirely to those persons and those types where there was pre-existing N antibody

Case 11's serum contained heterologous C.F antibody to type-3 virus in the absence of N antibody at 1/8 dilution of serum Similar observations were made by Melnick (1955) and Hammon et al (1955) Attention was directed by Mayer (1955) to possible reasons for cross-C F reactions between the three poliomyelitis viruses when unpurified concentrated virus suspensions are used Mayer et al (1957) have shown that highly purified suspensions of the three viruses have type-specific C F reactions with human convalescent sera

Of the vaccinated children, case 1's serum showed no complement fixation with any poliovirus With the test in use here it has been found that primary immunisation with two doses of vaccine does not appear to give rise to detectable levels of C F antibody in the absence of diagnosed infection Exceptions do occur, but in such persons it has been impossible to rule out antecedent subclinical infection Some recent tests in collaboration with Dr J O'H Tobin and Dr A D Macrae have shown that a third dose of vaccine is generally followed by the appearance of all three types of C F antibody How long these C F antibodies persist is not yet known

When suspensions of unheated live virus are used as antigens in the poliomyelitis C F T, homologous C F antibody often appears slowly in the sera of persons who have not before been infected by any poliomyelitis virus (Black and Melnick 1954, Le Bouvier 1955, Schmidt and Lennette 1956) The development of heterologous C F antibodies annuls the diagnostic value of a single convalescent specimen of serum, but, because of their rapid appearance, a rise in titre of homologous C F antibody can be demonstrated in a substantial proportion of cases, in felicitously spaced sera, when suitable virus suspensions are used (Schmidt and Lennette 1956)

The problem is of practical importance, now that widespread immunisation of children is being practised The evidence presented suggests that primary immunisation increases the frequency with which heterologous C F antibodies appear in such children's sera when they are infected by a poliovirus

C F antibodies decrease in time and may become undetectable after a few months (Lennette and Schmidt 1957) Heterologous C F antibody tends to wane even more rapidly Since the date of infection is not known for any of the children investigated, it is possible that the low homologous C F antibody titres of the sera of cases 4, 5, and 17, as well as the absence of heterologous C F antibody from the sera of cases 3–5, are a result of such antibody decline

Conclusions

This small-scale investigation calls for suggestions rather than assertions, but there is some evidence that

(1) Infection superimposed on primary poliomyelitis immunisation causes in some children a N-antibody response to the infecting virus, similar to that of a third dose of vaccine

(2) It is essential to obtain paired sera from immunised children when investigation by the C F technique for poliomyelitis is required

(3) The C F T is still of value in the diagnosis of poliomyelitis infections in children who have received two doses of vaccine, but recent tests on sera obtained a *fortnight* after a third dose of vaccine suggest that the C F T may be of little or no value in diagnosing subclinical poliomyelitis infections during this period

Summary

Serological tests for neutralising and complement-fixing antibodies were made on two small similar groups of children one group had received two doses of poliomyelitis vaccine in 1956, and the other group had been registered but was not yet vaccinated

The investigation was made a few months after a poliomyelitis epidemic in 1957

In children who already have been immunised with two doses of vaccine the C F T for poliomyelitis may be of diagnostic value, but only when paired sera are examined

Recent tests made on sera taken a fortnight after a third dose of vaccine indicate that the C F T will be of little or no diagnostic value during this period

Infection a year after immunisation with two doses of vaccine causes in some children an N-antibody response to the infecting virus, similar to that of a third dose of vaccine

I wish to thank Dr J D Kershaw, area medical officer for North East Essex, and Dr Eleanor Singer, assistant county medical officer of health, for their help, Dr R D Pearce, medical officer of health for Brightlingsea, and his staff, without whose cooperation this investigation would not have been possible, Dr W C Cockburn, director, Central Public Health Laboratory, Dr F O MacCallum, director, Virus Reference Laboratory, and Dr C C Spicer, who randomised the registered children

International Requirements for Poliomyelitis Vaccine

International requirements for the production and control of the Salk type of poliomyelitis vaccine have been formulated by a group of experts meeting recently in Geneva under the auspices of the World Health Organisation and the chairmanship of Dr J H S Gear In the past difficulties have often been put in the way of the free exchange of vaccine because of differences in the manufacturing and control methods applied in the country of origin and in the country wishing to use the vaccine When finally accepted, the new requirements are expected both to *facilitate the international exchange* of vaccine and to *provide guidance* and assistance to countries wishing to start production and control of vaccine This is particularly important now because in many countries where poliomyelitis was formerly rare, there have been severe epidemics in recent years

Other biological substances such as yellow-fever and cholera vaccine, blood and plasma, will be the subjects of similar recommendations for production and control requirements to be formulated by other W H O study groups during the coming *months This work is a new development in one* of W H.O 's most important programmes, that of biological standardisation In cooperation with more than 100 laboratories in different parts of the world, W H O has so far established about 50 new biological standard preparations, ranging from diphtheria antitoxin to a whole series of antibiotics This has made it possible for these substances to be measured and described in terms of international units accepted throughout the world

STAFF-LOCATION SYSTEMS SUITABLE FOR HOSPITAL USE

H C ELLIOT
B.A., B Com. Durh *
RESEARCH ASSISTANT, REGIONAL PHYSICS DEPARTMENT

J M A. LENIHAN
M.Sc Durh., Ph.D Glasg, A.M I.E.E, F Inst.P
REGIONAL PHYSICIST

WESTERN REGIONAL HOSPITAL BOARD, GLASGOW

IN a large hospital much of the work is done with the help of the telephone. An efficient communication system is an important part of the structure and one which is seldom provided. Existing installations in many hospitals are unsatisfactory for the following reasons

(1) At certain times of the day the switchboard becomes overloaded and no lines are available for incoming or outgoing calls

(2) Even when lines are available, the switchboard operators are often so busy that there is delay in dealing with calls

(3) Much time is wasted in finding members of the staff required for a telephone call Nurses and other skilled people are often used as messengers

(4) Telephone bells make an unwelcome noise in the wards

Staff-location Systems

One of the principal defects in existing hospital communications is the lack of a satisfactory method of finding an individual and bringing him to the telephone to answer an incoming call The staff of a large hospital may include 50–100 people who are often sought for this purpose, on many occasions only one person is competent to deal with a particular inquiry or request. The problem of finding an individual, who may be anywhere in a large building, without disturbing anyone else, is technically difficult and until recently has never been satisfactorily solved

A study of this matter was begun in the Regional Physics Department in 1953 at the suggestion of Prof C. F W Illingworth The first step was to write an outline specification of the equipment required The ideal characteristics for a staff-location system were decided to be the following-

(1) It should be silent

(2) It should attract the attention of the individual who is being sought but not of anyone else

(3) It should operate at every point in the building

(4) It should not require any attention or concentration on the part of the staff who use it.

No conventional telephone installation will meet these requirements, nor will any system of loudspeakers or coloured lights Consideration was therefore given to the possibility of pocket receivers, each tuned to a particular frequency and actuated by signals under the control of the telephone-switchboard operator Such a system appeared technically feasible, and inquiries were made of several manufacturers A voluminous correspondence ensued, but by the middle of 1955 it was apparent that none of the firms approached was in a position to do what was required

Towards the end of 1955 it was learnt that two firms, Multitone Electric Co Ltd. and British Communications Corporation Ltd, were engaged in developing staff-location systems answering to the specification outlined above, using the magnetic induction method This is a simple and surprisingly effective way of transmitting signals to any place inside a building It uses the following apparatus:

(1) A continuous wire attached to the outside of the building and forming a loop

(2) A transmitter connected to the ends of the loop

(3) A control unit placed near the main telephone switchboard.

(4) Pocket receivers using transistors for detection and amplification.

The external wiring is easily done. Aluminium wire about 3 mm in diameter covered with a 1-mm layer of polyvinyl chloride is a suitable material, being cheap and durable For a six-storey building of 19th-century construction a single loop at second-floor level will often be adequate For more modern buildings, containing a lot of structural steelwork, subsidiary loops may be necessary to eliminate dead spots inside It is usually convenient to fix the wire to the outside walls with staples every few yards but it can equally well be attached to the skirting boards or the inside walls

The transmitter is an electronic device generating alternating current at several frequencies one for each receiver. Once installed the transmitter needs little attention

The control unit is a small box with switches or push-buttons corresponding to the various frequencies obtainable from the transmitter

Each receiver is tuned to a particular frequency By pressing one key on the control unit the switchboard operator sends through the loop a signal which will be detected by only one receiver The normal practice is to transmit a buzzer signal, which advises the recipient to go to the nearest telephone to take an incoming call Facilities for speech transmission are also available but they are not likely to be of much use in a hospital Two-way communication is not yet possible

The following systems are now being made in Britain

Multitone Staff-Location System (Multitone Electric Co Ltd., 12–20 Underwood Street London N 1) installed at St Thomas's Hospital, Westminster Hospital St George's Hospital, Manchester Royal Infirmary &c

Radiopage (British Communications Corporation Ltd Exhibition Grounds. Wembley) installed at Western Infirmary Glasgow Royal Mental Hospital Glasgow, The London Hospital. &c.

Selectacall (Westrex Co Ltd Liberty House Regent Street London, W 1) installed at Duchess of York Hospital for Babies Manchester

Another system using V H F radio transmission instead of magnetic induction, has been announced but not yet installed in a hospital

Page Boy (Cotterill-Ginn Ltd, 13 Suffolk Street. London, S W 1) Signals are transmitted from suitably placed radiators, each containing a small oscillator and an aerial The radiators are connected to the control unit by lead-covered cable. no loop is placed round the building

Further details of these systems are given in the table

Other manufacturers are known to be developing staff-location systems, but details are not available.

---

* Now with J and P Coats Ltd., Paisley

DETAILS OF STAFF-LOCATION SYSTEM

—	Multitone	Radiopage	Selectacall	Page Boy
Size of receiver (cm)	14×3	19×7×2	13×5×2	15 0×7 0×2 5
Mass of receiver (g)	140	225	150	175
No of separate frequency channels *	36 or 56 (different models)	50	50 or 100 (different models)	141
Frequency band used by transmitter	2–15 kc/s	75–87 kc/s	155 kc/s	465 mc/s
Method of frequency selection	Tuned circuit in receiver	Crystal-controlled filter in receiver	Tuned reeds in receiver	Tuned circuit in receiver
Power supply for receiver	Mercury battery	Mercury battery	Hearing-aid battery	Rechargeable battery
Estimated life (wk)	8–10	10–12	7–8	
Cost of battery	*2s 6d*	*7s 6d*	*3d*	
Cost of transmitter and control unit	From £125 †	£475	£225 †	§
Cost of each receiver	From £18 18*s* †	£25	£24 †	£21 15*s*
Nature of signal	Buzzer ‡	Buzzer and speech	Buzzer	Buzzer ‡

* It is often convenient to extend the capacity of the system by allocating the same frequency to two or more receivers, using a simple code to provide separate calling signals

† Also available on ten-year lease, with quarterly rental

‡ Speech signal also available by pressing switch and holding receiver to ear in response to special calling tone

§ Modulator unit £52 10*s* Radiators each £11 5*s* The number required will depend on the size and shape of the building A typical 500-bed hospital would probably use at least 20 radiators Battery chargers £25 10*s* for every 12 receivers

Post Office Licence —Each of these systems requires a special licence from the Post Office, at a charge of £2 for five years

Trial and Results

A practical trial of a magnetic-induction system was made during 1956 and 1957 at the Western Infirmary of Glasgow The external wiring of the building was completed, with contractor's labour, at a cost of under £300 A complete set of equipment was supplied on loan by the manufacturers A research assistant (H C E) spent about six months collecting data before and after the installation of the personal calling system

EXISTING TELEPHONE INSTALLATION

The Western Infirmary has two main telephone systems

(1) A Post Office installation consisting of a two-position switchboard with 17 exchange lines (of which 7 are available for outgoing calls only) To this switchboard 118 extension telephones are connected

(2) A private automatic exchange for internal calls only, with 123 extension telephones There are smaller installations in various departments of the hospital

A survey made by the Post Office telephone department showed that the number of exchange lines provided for the hospital was about right for the volume of traffic, but that a larger switchboard, with more operators, was necessary for an efficient service at peak hours

Telephone Traffic Handled by Switchboard

During the busy periods (from 9 A M to noon and from 2 P M to 5 P M) in one week a note was made of the destination of each call passing through the switchboard to a ward, department, or individual in the hospital Some of these calls originated outside the hospital and some inside, calls passing out of the hospital were not recorded Of the 1700 calls noted in this way 44% were for wards, 44% for departments, and 12% for named individuals

Telephone Traffic in Ward Corridor

Observations were made on 200 incoming calls to a busy surgical unit Of these 200 calls, 107 were inquiries about the progress of patients, usually from relatives or from doctors outside the hospital Of the remaining 93 calls, 46 were for members of the medical staff of the unit In 19 instances the person sought was found in the unit, with an average delay of 1 5 minutes In 27 instances the person sought was not found in the unit the average time elapsing before this information was given to the caller was 1 7 minutes

In this small sample 41% of the doctors sought were found in their own units A similar inquiry covering other parts of the hospital gave a result not significantly different of 100 incoming calls to switchboard for named individuals the caller was connected at the first extension tried by the operator in 59 cases, at the second extension tried in 27, at the third extension tried in 10, at the fourth extension tried in 2, and at the fifth extension tried in 1 case 1 caller rang off before the connection was made

Waiting-time and Talking-time

The time occupied by the 200 above-mentioned incoming calls was 335 minutes, consisting of 62 minutes' ringing, 148 minutes' waiting for the person required to reach the telephone, and 125 minutes' talking In other words, of the total time for which telephone circuits were occupied, 19% consisted in waiting for someone to answer the bell, 44% waiting for the person required to come to the telephone (total waiting-time 63%), and 37% of conversation between the caller and the person sought

PERSONAL CALLING SYSTEM

When these inquiries had been completed the personal calling system was installed Fourteen receivers were issued on Nov 5, 1956, and others were gradually put into use up to a total of forty-five, leaving five as a reserve stock to cover breakdowns The control unit was fixed in the switchboard room, and the operators quickly became familiar with their new duties

The allocation of receivers was carefully considered in the knowledge that initial mistakes would not be rectified without difficulty and annoyance After studying the results outlined above it was decided that receivers should be issued to the following groups of staff

(1) *House-officers* in medical, surgical, gynæcological, and casualty units These members of the staff have many responsibilities in the day-to-day conduct of the wards and are often hard to locate This is particularly true on receiving days, when the residents are exceptionally busy and outside calls (about the admission of patients) are many

(2) *Ward sisters* —Half the calls coming to the wards are inquiries about the progress of individual patients When the sister, or her deputy, has a personal receiver in her pocket, such inquiries can be handled very efficiently The switchboard operator, on receiving a call for one of the wards, asks the caller if he is inquiring about a patient If he is, the operator presses a switch on the control panel to transmit a buzzer signal heard by the sister or the nurse for whom it is intended The recipient then goes to the nearest telephone and speaks to the inquirer

(3) *Individual members of the hospital staff*, including the medical superintendent, the matron, the administrative officer, the catering officer, and a few doctors whose duties extend to many parts of the hospital

(4) *Duty anæsthetists*

Impressions of the New System

The issue of personal receivers produced an immediate improvement in the efficiency of the hospital telephone system The following subjective reactions were noted

(1) *Switchboard operators* reported that persons carrying receivers could be located in a fraction of the time normally required

(2) *Practitioners* outside the hospital commented on the speed with which the receiving physicians and surgeons could now be found, in welcome contrast to the long delays previously experienced

(3) *Ward sisters* reported that their corridors had suddenly become quieter Where a full issue of personal receivers has been made, the telephone bell seldom rings, because most of the calls are notified individually to the people concerned, about 75% of the calls coming to a ward unit are intended for either the resident or the sister

Objective Tests

From the information already presented it will be clear that a major source of inefficiency in the telephone system is the long delay before a call is answered by the person sought Any improvement here will materially ease the switchboard operator's burden and will increase the amount of traffic that can be handled at busy periods of the day With these considerations in mind an objective assessment of the calling system was attempted by making surveys of 500 calls for persons carrying receivers, and of 200 calls during the same period for persons not carrying receivers The difference between the numbers of calls studied in these two surveys was due to the fact that, by the time that the observations were made, most of the people likely to receive a lot of calls had been issued with personal receivers Consequently the number of calls for individuals outside the network was relatively small

The significant parameter was judged to be the time required to locate the recipient of the call and bring him to the telephone The result of the comparison was ,

200 calls using ordinary telephone system	average delay 63 seconds
500 calls using personal receivers	average delay 25 seconds

Further analysis showed the following differences

AVERAGE DELAY BEFORE BEGINNING OF REPLY TO CALLER

Type of call	Ordinary telephone (sec.)	Personal calling system (sec.)
Calls for doctors	80	35
Inquiries about patients	54	15

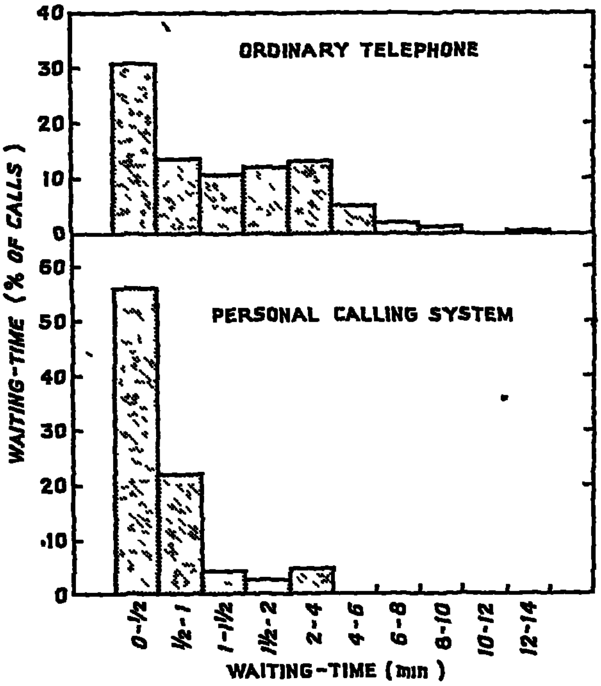
Since the talking-time is not appreciably different whether the call is announced by a personal receiver or by a telephone bell, the following comparison may be made

	Ordinary telephone	*Personal calling system*
Average waiting-time (sec.)	63	25
Average talking-time (sec.)	38	38
Average total time per call (sec.)	101	63

The information collected in these two surveys is displayed graphically in the accompanying figure, which shows that the operators sometimes spent as long as 14 minutes in trying to find a member of the hospital staff for a telephone call When the personal calling system was installed, the operators were advised not to wait longer than 2 minutes for a reply from the person sought This restriction of waiting-time was observed in all but a few instances, when the operators were too busy with other calls Even so, the longest delay before completion of a call or dismissal of the caller was no more than 4 minutes The proportion of calls not completed because the recipient could not be traced was as follows

Personal calling system	56 of 500 calls (11%)
Ordinary telephone	22 of 200 calls (11%)

These figures indicate that everyone responded to the personal-receiver call within the time allowed The residue of 11% presumably represents the proportion of people called who were out of the hospital at the time



Waiting-time in connection with ordinary telephone and with personal calling system

General Observations

Cost—The initial cost of a complete installation may be estimated from the figures given above Other factors, including reliability and ease of maintenance, should also be considered if knowledgeable advice is available The cost of the wiring depends on the system chosen and on the layout of the building Detached blocks can be connected to the main loop by buried cables

Number of receivers needed—Our experience suggests that personal receivers should be issued only to people who will often be required to answer telephone calls and whose duties take them to many different places in the hospital—namely, house-officers and duty anæsthetists, ward sisters, and peripatetic officials (possibly including clerk of works, catering officer, administrative officer, and night sister)

Interference—All the calling systems mentioned here operate at frequencies causing no interference with electroencephalographs, electrocardiographs, and other sensitive equipment likely to be found in a hospital

Before a staff-location system is introduced, the local telephone manager of the Post Office should be asked to report on the condition of the hospital's communication facilities in relation to the traffic handled A further survey should be made in the hospital by an investigator trained in the technique of work study It will often be found that useful improvements can be effected at little or no cost by rearranging the existing installation These inquiries will also provide a basis for administrative decisions on the purchase of a calling system and on the allocation of receivers The cost of the investigations should not exceed £150, even in a very large hospital

Summary

Staff-location systems suitable for use in hospitals have been devised by several manufacturers

Technical features of the equipment now available are described and the results of a practical trial made in a large teaching hospital are reported

The investigation described here was made possible by a grant from the Nuffield Provincial Hospitals Trust on the advice of its Scottish Advisory Committee We are grateful to the board of management for Glasgow Western Hospitals for permission to carry out trials in the Western Infirmary, where we received much assistance from the medical superintendent as well as from members of the medical, nursing and administrative staff We received expert and timely advice on many aspects of the work from Mr W A Gay, of the department of industrial administration, Royal College of Science and Technology, Glasgow, and from members of the Telephone Manager's staff, Glasgow area The apparatus used in the tests was supplied by British Communications Corporation Ltd

---

BIRTHDAY HONOURS

The list of honours published on June 12 contains the names of the following members of the medical profession

O M

Sir Macfarlane Burnet, M D Melb, M D, SC D Cantab, F R C P, F R S
Director, Walter and Eliza Hall Institute, Melbourne, professor of experimental medicine, University of Melbourne

K C V O

John Douglas McLaggan, C V O, M B Aberd, F R C S

K B E

Charles Ritchie Burns, O B E, M D N Z, F R C P
Physician and cardiologist, Wellington Hospital, New Zealand

Frederick Horace Smirk, M D Manc, F R C P, F R A C P
Professor of medicine, University of Otago

Knights Bachelor

Brigadier John Smith Knox Boyd, O B E, M D, LL D Glasg, F R C P, F R S
President, Royal Society of Tropical Medicine and Hygiene, formerly director of pathology, War Office, and director of Wellcome Laboratories of Tropical Medicine

Colonel Aldington George Curphey, C B E, M C, E.D, M D Queen's Univ, Canada
President, Legislative Council, Jamaica

John Carew Eccles, M B Melb, M A, D PHIL Oxon, F R A C P, F R S
Professor of physiology, Australian National University, Canberra

Benjamin Thomas Edye, C B E, CH.M Sydney, F R C S, F R A C S
Consulting surgeon, Royal Prince Alfred Hospital, Sydney

Brigadier Kenneth Barron Fraser, C B E, E D, M B Sydney, M S Queensland, F R A C S
Late Australian Military Forces, for public services

Eric William Riches, M C, M S Lond, F R C S
Surgeon and urologist, Middlesex Hospital, London

C B (Military)

Air Vice-Marshal Lancelot Miller Corbet, C B E, M B Melb

Major-General John Huston, M B Belf, F R C S E, Q H S

Surgeon Rear-Admiral Richard Louis Gibbon Proctor, M D Dubl, F R C P I

C B (Civil)

George Edward Godber, D.M Oxon, F R C.P
A deputy chief medical officer, Ministry of Health

C.M.G

James Malcolm Liston, M B Glasg
Director of medical services, Tanganyika

Richard Murchison Morris, O B E, M D Lond
Secretary for Health, Federation of Rhodesia and Nyasaland

C V O

James Crooks, M B Edin, F R C S

C B E (Military)

Colonel Robin Arthur Smart, M B Aberd, R A.M C.

Air Commodore Denis Aymard Wilson, A F C, M R C.S, F F R, Q H S, R A F

C B E (Civil)

Daniel Fowler Cappell, M D Glasg, F R F P S
Professor of pathology, University of Glasgow

Charles Skinner Hallpike, M B Lond, F R.C P, F R C.S, F R.S
Director, Medical Research Council otological research unit, National Hospital, Queen Square, London

Jean MacIver Mackintosh, M D Glasg
Administrative medical officer of health for maternity and child welfare, Birmingham

O B E (Military)

Lieut -Colonel Warren John Boyd, E D, M B, R N Z A M C

Lieut.-Colonel Denis Henry Dryburgh Burbridge, M R C.S, R A M C

Group-Captain Roy Brasmere Davis, M B Melb, R A A F

Wing-Commander Frederick Latham, M D Manc, R A F

O B E (Civil)

Basil George Brooke, M D Dubl
Chairman, Medical Board, Manchester, under the National Service Acts

Alexander Mackay Calder, M B Edin, F R C S E
Surgeon, Newtownards Hospital, Co Down

Herman Robert Frederick, M B Edin
General practitioner, Port Talbot

Ernest Wightman Ginner
Physician, Sunnybank Hospital, Cannes

Stanley Augustine McDonnell, CH M Sydney
For services to the community in the Balonne area, Queensland

Alasdair McKelvie, M B Edin
Lately specialist leprologist, Ghana Ministry of Health

Lily Margaret O'Hanlon, M R C S
Head of Pokhara Mission Hospital, Nepal

Cecily Mary Wise Pickerill, M B N Z
Formerly plastic surgeon, Wellington Hospital, New Zealand

Robert Merrick Lloyd Still, M R C S
Medical superintendent, Mental Hospital, Barbados

Eric Blake Wild, M B Lond, F R C S E
Doctor-in-charge, Church Missionary Hospital, Isfahan

M B E (Military)

Squadron-Leader Charles John Williamson Soutar, M B Lond, R A F

M B E (Civil)

Charles Donald Ferguson, M B Glasg, J P
For political and public services in Ross and Cromarty

Arthur Stephen Garrett, M B Lond
Medical officer, Leprosy Service, Eastern Region, Nigeria

Gavin Muir, M B Glasg
Member, Medical Board, Newcastle, under the National Service Acts

In England Now

A Running Commentary by Peripatetic Correspondents

WHY are we doctors often so unpredictable? Why does our attitude to our patients vary so much according to their environment? Of course I had always realised that a few doctors were inclined to treat their patients in hospital like rather deaf overgrown children, but *I* certainly didn't. However it has been brought home to me very kindly but pretty plainly that perhaps I am no better than the rest.

My patients, two rather charming elderly ladies, had been to see a physician in his consulting-room and were delighted with the way he carried out the examination. In fact we united in saying what a thoroughly nice person he was. But then came the pill in the jam. "Why, doctor," they asked me, "is he so different when you are an inpatient in hospital? He shouts across the ward. He is always in a hurry. His actual treatment is above reproach, but you are no longer a person, you are just a number, and when tackled he admitted it himself." I murmured the usual platitudes and left it at that. But later I remembered that at different times both these old ladies had been in hospital under me, and how had I treated them? Certainly not as I treated them when I visited them at home. I had asked them questions but had looked to the nurses for a reply. I had prescribed treatment but had left it to the Sister to explain what it was meant to do. I had spoken to *them from the foot of the bed. It is* easy enough to say that I find a hospital ward inhibiting, to blame the hospital staff, and feel that they tend to serve the patient up to us rather like a broken piece of machinery which, acting on our instructions, they are endeavouring to clean up, polish, and put in working order. They appear to resent a request to leave us alone with the repaired article, and on busy days it is easier to acquiesce, to talk over the patient's head, to forget that removal from home to hospital has not changed an intelligent person into someone who is unable to hear easily or answer questions.

My patients never hinted that they thought I was at all to blame. They are kinder than their doctor and would not hurt my feelings for anything, but it made me think, and what I thought wasn't exactly pleasant.

* * *

Twenty years ago, the gynæcology in my hospital was done by the general surgeon, because there was no gynæcologist at that time. The theatre nurse was one of the loveliest girls I have ever seen; she was known as "the houseman's heartbreak", and her beauty was equalled by her competence. I was engaged in the removal of two ruptured dermoid cysts, the cyst wall was adherent to both large and small intestine. Finger dissection was impossible, and the precarious process of separating the adhesions at the point of a sharp scalpel was arduous. At last I got the operation successfully completed, and closed the skin, remarking somewhat sententiously to the nurse, "Well, Nurse, *finis coronat opus*, if you know what that means." She replied, "Yes, Sir," and I asked, "Well, what *does* it mean, Nurse?" She answered, "I don't know any Latin, but I suppose it means it looks all right when the skin is closed."

* * *

Maybe I do look a square to the hep cats. Theirs is a hasty judgment. My bathroom mirror would tell a different tale, a more curvaceous profile would be hard to find, if you are not too fussy about segmental distribution. Anyway, a man should carry all before him with a permanent dignity of mien denied to the overpublicised fallout of the film stars, or his more transient competitors in the third trimester of expectant joy. But the hep cats are more scornful of my mind than mere flesh. It is positively indecent that Father should still have a *yen to dig* that crazy rhythm, and frantically pathetic when I try. Five stone and thirty years ago was where I came in, with my Oxford bags boring holes through the ballroom air. The bags are now under my eyes, the fireside chair needs re-springing, but somewhere up in the frontal lobes the old arterioles jive into spasm when the offbeat pulses stir up the past. Skiffle sends me. Sends me back, not only to the sentimental memories of the sweetest music this side of Heaven and the decorous gaiety of swing, but schizophrenically back to the half-lit cellars of Harlem, the throbbing primordial drumbeat, that curious scent, the dime-a-dance magnetic contact with inborn basic rhythm. No, Siree, only the years elbow me out of the groove. But I am fighting back.

As I mushroom over the bar stool, swilling the talc dust from my tonsils, and doing a surreptitious hand jive, I think how unenterprising are the youth of today. Their terminology is so boringly monotonous. If they have chosen to call themselves hep cats, why stop there? There is the whole range of veterinary pathology to give descriptive colour to their convulsions. Encephalomalacia has a pleasant syncopation in its own right, but they could really go to town on its synonym, crazy chick disease. What scope for the pop singer to shriek in his opisthotonos "Dig that crazy rhythm, Chicks, I've crazy chick disease." And the touching euthanasia of his partner's request to be put down forthwith. Strychnine seems to be doing the job quite adequately; cyanide would be too good for some of them.

Localised copper deficiency is just inviting swayback at midnight ballroom orgies. Beware of the hep with hepatitis, foot-stab is the recognised treatment in the best veterinary and chuckerout circles. Foot-and-mouth is the cry for song and dance in the cabaret; foot-rot marks the sitters out. Surely a cysticercus would be a more attractive title than a jam session on a tape recorder, and much more hospitable. If the idea catches on, just think of the vibriosis on the floor, the warble of muted clarinets, the curled tongue trumpeters, the push and pullorum of jiving, the free range, the coolness of the cats. Those kids don't know they're alive yet. Wait till my new diet melts the corners off. I'll show them I'm no square.

* * *

On my last flight home from New York altitude went to my head and British reserve forsook me. There were, of course, extenuating circumstances, for the lady who took the seat beside me was at least 70 years old and travelling alone. Courtesy dictated that I should help her in every way. She had flown in from San Francisco and was going on to Mainz, her home until 1906, her command of the English tongue could hardly have improved since. My respect for her grew as she ordered a manhattan from the stewardess, but there lay my undoing—or was it perhaps the bourbon I had taken myself—for as the stewardess reappeared I offered the second, which to my surprise she accepted. Her tongue was loosened and her life story unfolded. Fifty years a chiropractor! Case-history followed case-history against the tamponade of aero-engines—worse than any surgical meeting. There was the governor of Alaska's daughter cured of blindness by cervical manipulation, and the lack of consideration in her husband who chose to be acromegalic without deviation of the spine. He died—and deserved to, or so I seemed to detect. Each case-history ended with the moral, monotonously drawn, "We must not jump at conclusions."

Chiropraxis now has a firm grip upon San Francisco, but it had not been without a struggle, for those villainous doctors (how thankful I was that I had not slipped so far as to reveal my profession) had done all they could in an endeavour to make it illegal. Eventually victory had been easy. Deft manipulation of the cervical spine had cured a boy who hitherto had squinted like an owl. It was only necessary to send him round the town to gaze each citizen straight in the eye, while at the same time displaying an early school photograph, for all prejudice to be overcome. The chiropractic law was passed.

I was thankful when we passed into cloud which disturbed our even flight. The flow of words gradually ceased, a hand moved surreptitiously to handbag and a *pill* was passed quickly into her mouth.

Overheard in out-patients (as chest physician wearing red goggles walks through to the X-ray department)—"Look, Mummy, that spaceman from Mars smiled at me."

Letters to the Editor

THE PLACE OF HUMAN BIOLOGY IN MEDICAL EDUCATION

SIR,—I read Dr. Tanner's article of June 7 with considerable interest. I have two objections, however, to his preclinical curriculum: it is too long and it is too vague. By the end of his second year the medical student should be ready to commence his clinical course and he should begin it with a sound knowledge of the development, structure, and normal functioning of the particular and peculiar creature on whom he is going to practise his skill as a doctor.

There is no sensible reason, although there are plenty of "academic" reasons, why he should not commence his anatomy, physiology, and biochemistry as soon as he enters the university. For all practical purposes he will have done enough chemistry and physics and general biology at school. Most of Dr. Tanner's curriculum could be included in a revised and reformed anatomy and physiology course extending over a two-year period, but however useful a knowledge of cellular biology, genetics, evolutionary theory, constitutional variability, and the use of statistical method may be, an accurate and complete knowledge of gross anatomy and of the basic functions of the body is essential. This does not mean that a great deal of detail could not be removed from the textbooks, but what is retained must be taught well and understood at the time it is being taught. I agree that further detail can most usefully be added later in relation to whatever specialty has been selected by the student, but this also applies to the whole content of the preclinical course.

A great deal of our present trouble is due to the tradition of teaching subjects such as anatomy, pathology, and biochemistry in water-tight compartments. Once these subjects are introduced into the curriculum they should remain in the curriculum and continue into postgraduate studies, but, as in other spheres, the method and timing of the introduction is very important. Once the essential framework of a logical and not over-ornate curriculum has been established there is a place for various subsidiary activities such as films, visiting lecturers, inter-departmental "brains trusts", &c., but these should not be looked upon as a means to make the fundamental process of learning the basic subjects more attractive. Grammar must come before rhetoric, and sound accurate knowledge must not be smothered in a foam of scientific enthusiasm.

The construction of a revised and up-to-date curriculum requires new textbooks written not in isolation but as units of a curricular library, and especially new teachers who take their responsibility as teachers as seriously as they take their research work or their clinical duties. The art of great teaching must be restored to its proper place. Teachers and textbooks can both be produced in time, providing a whole medical school is willing to attempt the experiment as a team, but there is little hope of much improvement by a process of uncorrelated departmental tinkering. We have been at that long enough.

Department of Anatomy,
The Queen's University of Belfast. JAMES H. SCOTT.

THE PREDICAMENT OF THE BLADDER

SIR,—The urinary bladder has a life of unparalleled hardship. In the male it is encumbered by the prostate; in the female it is buffeted by the fœtal head. Like many another mass-produced article, it is poorly finished—and substandard bladders with such obvious flaws as diverticula and ectopia vesicæ are still foisted on a long-suffering public.

The unfortunate organ is wantonly assaulted by the gynæcologist, the general surgeon, the urologist, the proctologist, the obstetrician, and the abortionist. Germs, tumours, and stones flourish within it, and its seclusion is rudely disturbed by bits of wire, knitting needles, and sundry other objects introduced by owners who are perverse, inquisitive, or just plain careless.

Its double function, to hold water and yet to pass water, makes a paradox which often confuses the young and inexperienced bladder—but even veteran bladders may fail in their duty through no fault of their own. To be incontinent, that is a misfortune which the bladder accepts with sardonic stoicism, only sorrowing at the misery which its defection may bring upon a kindly owner, upon a master who has treated it well. But retention: that is the culminating, and the cruellest, blow. Long and bitter experience has taught the bladder that this dread event is a herald of doom. It cries aloud in its agony and fear, and it will not be comforted. Neither faith nor potions will avail it now. The surgeon, and only the surgeon, can put an end to its torture.

Here, perhaps, is a dictum of our craft: "an obstructed tube is the only absolute indication for surgery". It matters not whether the tube is urethra or gullet, ureter or bowel, blood-vessel, windpipe, or bile-duct. We have no choice in this surgical variant of Hobson's Law.

It is curious that the bladder, in this moment of its greatest need, when it comes before the surgeon as a suppliant, should seek, so often, to deceive him. It is not above masquerading as an ovarian cyst, a pelvic abscess, or even a pregnant uterus. Two cases of this base ingratitude have recently come under my care.

The first was a man of twenty-seven who was admitted with pain in the perineum, high fever, and a bladder distended to the umbilicus. Small quantities of urine could be voided, with pain and difficulty, if he adopted the knee-elbow position. An X-ray showed a rounded opacity one and a quarter inches in diameter at the base of the bladder.

The patient was returned to the X-ray department with a request for oblique and confirmatory views of the "vesical calculus". No further radiographs were taken, but I was courteously reminded that the penis, photographed end-on, throws a circular shadow approximately one and a quarter inches in diameter!

The patient's retention was reflex, and his perineal pain was due to osteomyelitis of the sacrum. I subsequently drained half a pint of pus from behind his rectum and above the levator ani. The pus grew *Staphylococcus aureus*, and his convalescence was uneventful. He passed water normally from the seventh postoperative day.

The second patient was a sixty-year-old man who had passed no urine for forty-eight hours. His prostate was palpably enlarged and the distended bladder could be felt above it.

He was (and, curiously enough, still is) a Christian Scientist, and at first declined all aid. However, we felt that time was on our side, and a little later he allowed us to withdraw forty ounces of urine from his exasperated bladder. This was his only concession and he adamantly refused any operative interference.

For a week we eyed each other with mutual hostility. The catheter was removed on several occasions, but no urine escaped, the pain returned, the bladder was again palpable at the umbilicus. He then agreed to operation, provided that we would take a second opinion from Mr. X, his Christian Science practitioner. This we did, and a pretty bizarre opinion it was! Nevertheless, I feel bound to admit that Mr. X's views on the pathogenesis of this particular malady were no more absurd than my own.

When the patient was brought to the theatre, his bladder was still distended to the umbilicus, a phenomenon which we attributed to the withdrawal of his catheter some hours earlier—as a prophylactic against any last-minute repentance. A mid-line incision exposed a large swelling which was clearly not the urinary bladder. The peritoneum was opened, and the swelling proved to be an enormous cyst, filling the pelvis and squashing the unfortunate bladder into the left half of the abdomen. The cyst was removed without any great difficulty, and was shown to have originated in a presacral neurofibroma The bladder, relieved of its unwelcome neighbour, at once resumed its functions

I hope your readers will agree that there are several morals, as well as an extraordinary number of mixed metaphors, in this narrative

Barnet General Hospital,
Barnet.

INTESTINAL ANGINA

SIR,—I was very interested in your leading article of June 7 I must, however, take exception to your statement in the first paragraph—" and they must not be confused with the common abdominal radiation of cardiac anginal pain "

Cardiac anginal pain very rarely radiates to the abdomen. Typically this is retrosternal and may radiate to either chest, shoulder, or arm Less frequently it radiates to the jaw, and through to the back I have paid particular attention to this radiation during the last five years In only one case, proved at postmortem to have a cardiac infarct, did the pain radiate to the abdomen, even in this case there was a possible alternative explanation

This is a very important feature of cardiac anginal pain If it is accepted that this rarely radiates below the xiphisternum it becomes an extremely important differential diagnostic point

Chichester

JOHN D -WHITESIDE

SIR,—In reference to your editorial on " intestinal angina ", I should like to remark that what has been described recently by Mikkelsen under this term is the syndrome described many years ago by Professor Ortner and by myself and to which I gave the name of " intestinal angiospastic syndrome " A new name does not mean a new disease, particularly when that name will cause great confusion in clinical work

As I pointed out in my description,[1] the intestinal angiospastic syndrome occurs in individuals somewhat advanced in age and frequently after a prodromic period of vague abdominal disturbance It consists in sudden attacks of acute diffuse abdominal pain reaching its maximum in about one minute, lasting some ten or fifteen minutes and accompanied in its last phase by tympanism and sometimes by pallor, acceleration of pulse, and even collapse These attacks occur after meals when the digestive tube has been loaded with food, principally with foodstuffs producing gas through fermentation, and in some cases following exertion, mainly after meals It has to be distinctly differentiated clinically from cases of angina pectoris with epigastric pain and it is for this reason that the terms intestinal or abdominal angina are confusing I described the intestinal angiospastic syndrome as one of the syndromes manifesting atherosclerosis of the intestinal arteries, the other being acute mesenteric thrombosis which, in some cases, follows the attack of this angiospastic syndrome

Enlarging on the study of Ortner I pointed out the coincidence, in both these syndromes, of manifestations of angina pectoris and of atherosclerotic obliterans arteriopathy of the limbs, such manifestations in some cases following each other in time, as in a case described in collaboration with Dr Catsaras in this journal [2]

The work of the American authors you quote is important in directing our attention again to intestinal atherosclerosis and particularly in indicating the possibility of surgical treatment It is, however, necessary to stress the significance of the original clinical descriptions and to maintain the original terms through which the confusion with angina pectoris with epigastric pain is avoided Precision in terms is essential in clinical medicine

London, W 1

A P CAWADIAS

ADRENALINE CREAM

SIR,—I was surprised to read that Dr Hume Kendall and his associates (May 17) had expended so much effort in proving that adrenaline cream is ineffective in the treatment of degenerative arthritis of the spine I have never suggested, as Dr Kendall seems to believe, that the cream relieves the rheumatic syndrome by producing hyperæmia or analgesia when applied locally I have consistently stressed that adrenaline cream works *only* if it is applied to the myalgic or " trigger " spots of muscles in a state of spasm, when it relieves the pain of " fibrositis " and other forms of soft-tissue rheumatism

Since Good [1] first drew attention to them, the existence of trigger spots and their capacity to cause pain and disabilities commonly designated as " rheumatic " have been confirmed by several independent workers, notably by Bonico [2] Yet in those extensive trials of the cream which have given negative results, the treatment has never been applied to the myalgic spots [3]

Surely it is essential for the evaluation of any therapy that trials should be carried out in the manner indicated in the primary research As yet—after a decade—this has not been done, except by Howell,[4] who obtained a positive result

May I suggest to Dr Kendall and to others interested in the treatment of the chronic rheumatic diseases that if further trials are contemplated, the technique of treatment should be the one I have described [5]

London, W 1

LOUIS MOSS

COLOURED TABLETS

SIR,—The practice of colouring and coating pharmaceutical tablets has grown considerably during recent years, especially among companies which have begun to operate in Britain from overseas The *British Pharmacopœia* has hitherto resisted the inclusion of colour and coating except for good pharmaceutical reasons, such as protection against deterioration or the masking of unsightly colours in the natural material

The manufacturers claim that the improved elegance achieved justifies the new practice, and they also claim that it is necessary to enable the industry to compete in foreign markets So strong has this pressure become that the *Pharmacopœia* has now had to take the course of admitting the manufacturer's tablet, coating, colouring, and all, or not have it in the *Pharmacopœia* at all [6]

Some of us believe that the colouring and coating of tablets and capsules, except for the reasons formerly accepted, increases the danger of poisoning among children, though proof of such an assertion is difficult to obtain

A preliminary experiment was recently carried out in the Westminster Children's Hospital along the following lines

'Smarties', a brand of coloured sweets favoured by most children, were segregated into their constituent colours and offered, along with some specially prepared white ones, to children attending the clinics The dishes contained equal numbers of tablets and were randomly arranged on the tray The number of each taken during the experimental period was

[6] See *Lancet* April 5, 1958, p 726

Red	209	Orange	185	Brown	152
Black	145	Pink	132	White	132
Green	114	Mauve	111	Yellow	106

If white is regarded as a colour, the only marked preference is for red and orange

In a second experiment, a dish of mixed smarties—the normal assortment—was offered alongside white ones In this case the preference for the coloured tablets was of the order 2 1

It is true that the smarties are known and appreciated by the children and this gives a bias against an unknown white commodity, but it does seem reasonable to conclude that the more one makes medicinal tablets look like smarties, the more likelihood there is of children taking them

Experiments of different design are being prepared to remove some of the bias this preliminary experiment obviously has, and these we hope to publish in due course

STRUCTURAL DETAILS IN MYCOBACTERIA AFTER HYDROLYSIS

SIR,—The presence of soluble material (cytoplasm and external lipid layer) in the cells of mycobacteria has been held responsible for the difficulty in discerning morphological details within the cell [1] A method is here reported by which an insoluble specifically inert material containing undamaged cell walls and electron-opaque granules, was isolated from *Mycobacterium tuberculosis* after removal of the unstructured soluble cellular material

An eight-week-old culture of *Myco tuberculosis* H_{37} R_V grown in glycerin-broth, was heated for 30 min at 120°C and then harvested in 10 volumes (w/v) of *N*KOH solution and incubated for 2 hr on a boiling water bath under a reflux condenser The homogeneous highly turbid suspension that resulted after heating was washed with *N*KOH solution in the centrifuge (15,000 *g*) and the white residue allowed to digest with trypsin for 12 days at 37°C under toluol [2] The remaining insoluble material was washed with distilled water by centrifuging at 18,000 *G* and extracted with 50 volumes (*w*/*v*) of formamide for 6 hr at 100°C The stable suspension was separated in the centrifuge (20,000 *g*), washed and resuspended in distilled water The insoluble fraction obtained in this manner contained 10 5% nitrogen, 7% carbohydrates, and 17 9% ashes It represented 0 3% (dry weight) of the original bacillary material and was specifically inert when tested in vitro or in the animal (work to be published)

Examinations of the insoluble fraction showed, as revealed in the light microscope after staining,[*] non-acid-fast, transparent bacillary bodies which stained faintly pink with Ehrlich's dye and contained one or several metachromatic dark violet granules (fig 1*a*) By comparing the electron-micrograph of the insoluble fraction (fig 1*b*) with the images previously obtained by direct or ultra-thin section examinations of mycobacteria[3, 4], it may be seen that the treatment resulted in a strikingly increased permeability of the bacterial body to the electron beam The cells appeared like "flat collapsed sacs" which obviously represented the bacterial cell walls, and contained well-defined opaque granules resembling in shape and disposition the metachromatic granules viewed in the light microscope The alkali-trypsin-formamide-resistant granules, staining metachromatically and electron-opaque, can obviously be identified with the "volutin-metaphosphate" granules recently studied by Glauert and Brieger [5]

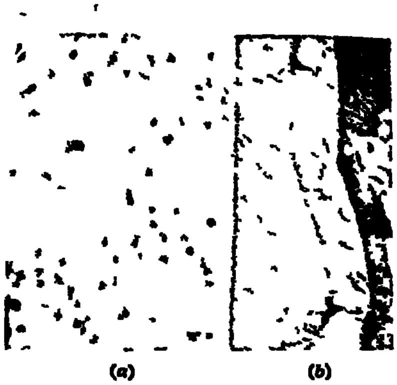

Fig 1—Insoluble fraction (*a*) photomicrograph (×2500), (*b*) gold-shadowed electron micrograph (×15,000)

A significant result concerning the intimate structure of these granules was noted when the insoluble fraction was subjected to a suitable treatment for 6 hours at 65°C with 0 5 *M* trichlorate acid and examined by the light and electron microscopes Fig 2[†] indicates that the metachromatic granules were thoroughly dissolved out in trichloracetic acid, while under the electron microscope there was no detectable change under these circumstances "Volutin" granules of mycobacteria are, therefore, not homogeneous, they contain at least two chemically separable constituents carrying respectively the metachromatic and electron-opaque characters

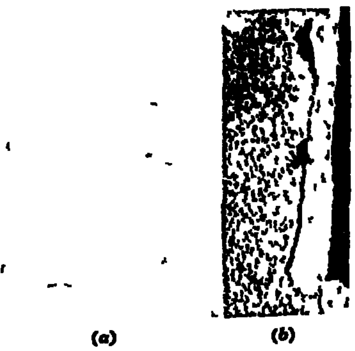

Fig 2—The insoluble fraction after trichloracetic-acid treatment (*a*) photomicrograph (×2500), (*b*) gold shadowed electronmicrograph (×8500)

G G GANCEVICI

UNEXPLAINED FACIAL SPASM

SIR,—Recently I was confronted with a curious case of facial spasm

A girl of 10 was referred to the Birkenhead Children's Hospital with a spasm consisting of depression of the mandible and retraction of the tongue, beginning an hour after extraction of two left lower molars two days before Deglutition was possible, but not mastication There was no other spasm, and no history of recent injury Dislocation of the jaw was excluded

On examination, the child could not move the jaw or tongue Chvostek's sign was positive on both sides in the distribution of the mandibular division of the 5th nerve Trousseau's sign was negative, and there was no carpopedal spasm Serum-calcium was 10 2 mg per 100 ml

The condition gradually abated over the next three days, after which the child could eat normally Chvostek's sign persisted for five days

It was suggested that the increased nervous irritability may have been due to facilitation at the synapses of the reflex arc, involving the trigeminal and facial nerves, and brought about by the persistent stimulation of the former nerve

WARREN DURRANT

ESSENTIAL FATTY ACIDS, LIPID METABOLISM, AND ATHEROSCLEROSIS

SIR,—Our interest was aroused by the article by Dr Kinsell and his colleagues (Feb 15)

Though we are not convinced of the cholesterol-depressing action of essential fatty acids in relation to atherosclerosis, our own observations confirm some of the propositions of Dr. Kinsell and his colleagues There is some evidence[1] of the direct conversion of linoleic to arachidonic acid we therefore used soybean oil, one of the richest sources of linoleic acid Meanwhile it appears[2] that the favourable cholesterol-depressing effect is limited to linoleic and arachidonic acids

10 patients (8 men and 2 women) with hypercholesterolæmia were investigated In 8, signs of coronary sclerosis were found (myocardial infarction, angina pectoris) 2 had hypercholesterolæmia without any clinical symptoms of vascular lesions In 3 patients the disease was complicated by diabetes, in 1 by hypertension The average age of the patients was 55·5 years

The first week after admission was a control period and the patients received a diet similar to the one they were accustomed to Blood samples were taken twice during this period

6 patients (group *a*) then received a diet providing 30 calories per kg of ideal body-weight, fat yielding 30% of the calories, protein 18%, carbohydrate the remainder All free fat was supplied as soya oil The vitamin-C intake was about 100 mg a day 4 patients (group *b*) received a diet isocaloric with that of the control period, but all free fat was supplied in the form of soya oil The average oil intake was 41 5 g a day

9 patients had this treatment for five weeks, and 1 for eleven weeks, and 1, as an outpatient, for ten weeks

---

[1] Mead, J F, Howton, D R *J biol Chem* 1957, 229, 575
[2] Hegsted D M, Gotsis A, Stare, F J *J Nutr* 1957, 63 377

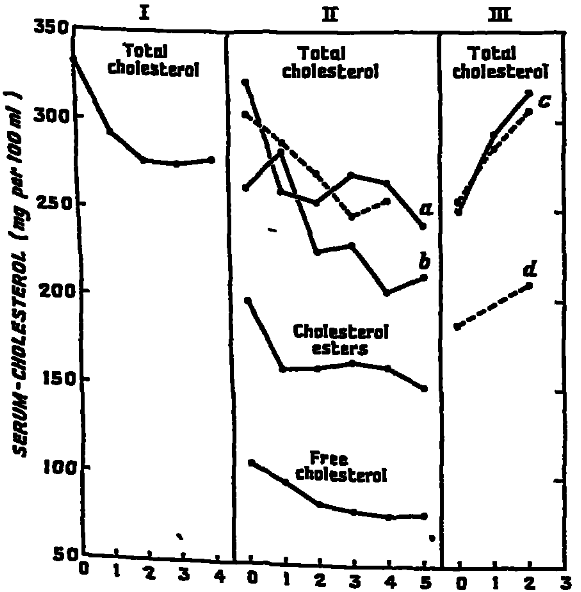

Fig 1—Serum-cholesterol levels before (I) during (II) and after (III) the period of soybean oil diet Broken line Findings in patient taking olive oil *a b, c, d* see text

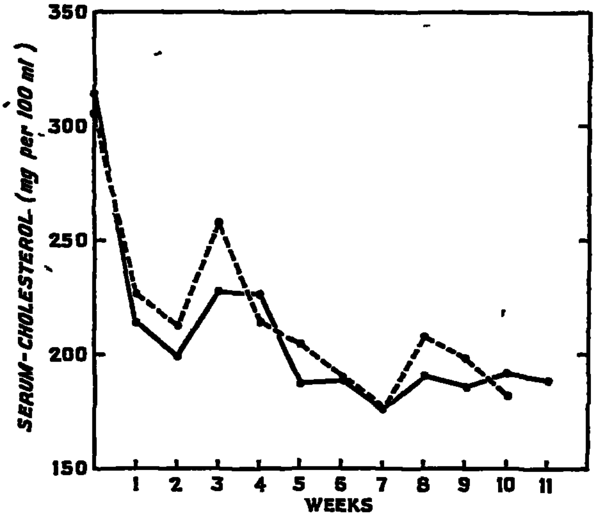

Fig 2—Serum-cholesterol changes in outpatient (broken line) and hospital patient (continuous line)

4 patients with hypercholesterolæmia who were admitted to hospital but did not receive the soya oil served as controls In another patient the soya oil was replaced by olive oil

The serum-cholesterol in the control patients reached a somewhat lower level than the initial values In the group receiving the soya oil (fig 1) an obvious fall in the serum-cholesterol level was noted, which persisted throughout treatment There was no substantial difference between groups *a* and *b* 2 patients were followed after the dietotherapy had been stopped and a rise of the serum-cholesterol was noted, though in one patient (*d*) the caloric value and fat content of the diet remained unchanged and in the second patient (*c*) the caloric value of the diet was even reduced from 2700 to 1800 calories, and the fat content from 95 to 65 g, but the soya oil was replaced by animal fats

All our patients receiving the soybean oil felt better, though the blood-coagulation and the lipoprotein pattern remained unchanged. A shift of the lipoprotein fractions from beta to delta was insignificant We think that the analogous results obtained in an outpatient exclude the possible effect of bed rest and other non-dietary factors on the cholesterol level (fig 2)

J VAVŘÍKOVÁ

PREMEDICATION FOR OUTPATIENT ELECTROCONVULSION THERAPY

SIR,—Electroconvulsion therapy (E C T) for specific mental illnesses is being increasingly used with success in outpatient departments, not only in order to save patients admission to hospital but also to allow them to continue their work whilst receiving such treatment Further, if given in a general hospital it is acceptable to people who, although in urgent need of it, could not accept what they regard as the “ stigma ” of attending or entering a mental hospital

In spite of these advantages, however, there remains the very real problem of the apprehension and anxiety which precedes E C T even when modified with thiopentone and suxamethonium chloride, as is our practice It was to deal with this problem that a small clinical trial was carried out, and, although no control group has yet been studied, the results achieved were of great practical value

30 patients, all attending for outpatient E C T at a general hospital and all complaining of such pretreatment anxiety

and apprehension (all having had one or more modified E C T s) were given a small supply of methylpentynol carbamate ('Oblivon C'), with instructions that on the morning of treatment, two 'Ovets' (200 mg) should be taken on rising and two more about an hour before attending hospital—i e, about 1 30 P M

There was a striking improvement in the attitude of most of these patients Grading of their reactions was rated as "much improved", "improved", "no change", or "worse" 20 patients claimed to be "much improved", 8 more were "improved", only 2 patients felt no different, and none felt worse

I am aware of the failings of such a trial, both from the smallness of its numbers and the absence of a control group These will take time to rectify, although it is hoped to do so

The importance of these apparently excellent results lies not only in the relief of the pretreatment fears but also in the fact that patients urgently requiring such treatment now feel able to accept it, whereas previously their very real fear and terror prevented them from doing so Hence this letter

WORLD HEALTH ASSEMBLY

SIR,—In your note of June 7 on the tenth annual commemoration session of the World Health Organisation, you report that Dr Brock Chisholm, lately director-general of W H O, said that the Organisation had come to be widely recognised for efficiency This was, he thought, due to the unique character of the Executive Board, whose eighteen members act purely as health experts and not as representatives of governments "Any attempt to convert the Executive Board into a political body would threaten the future of the Organisation"

Some considerable experience in the conduct of small voluntary associations leads me to believe that those responsible for such associations are likely to achieve efficiency similar to that of W H O, on its more important level, whenever they adopt the expedient of accepting guidance from advisors not primarily concerned with authority

Braziers Park,
Ipsden, Oxon
J NORMAN GLAISTER

A USEFUL ACCESSORY SUTURE

SIR,—I think it might interest people to know about a little procedure or "dodge" I have used for many years to facilitate the removal of sutures It is particularly useful in children, and has come through many years' trial very satisfactorily

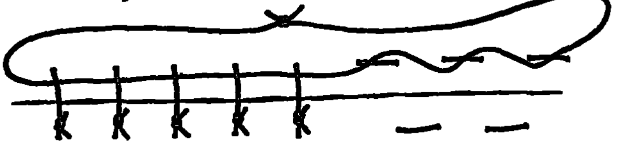

Fig 1—Continuous thread in position

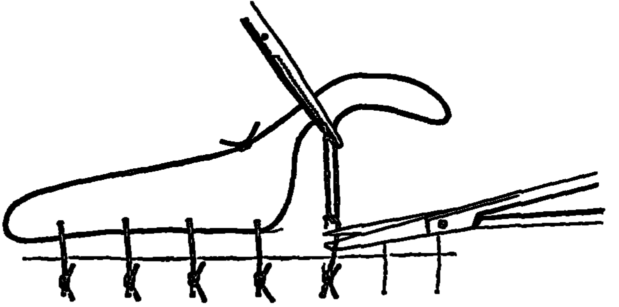

Fig 2—Removal of sutures

A continuous thread of a material different in texture and colour from that used for the skin suture is passed under each skin suture The thread therefore runs parallel with the incision and lies quite loosely in between each two sutures (fig 1) Removal is facilitated (fig 2), the effect of the œdema round the sutures is completely offset, and, even in a poor light, sutures may be removed quickly and painlessly even in a very young or very nervous patient

Liverpool, 1
BRYAN MCFARLAND

PROTHROMBIN ESTIMATION BY THE TWO-STAGE METHOD

SIR,—Dr Wright and his colleagues (May 31, p 1157) report evidence of slow coagulation when heparinised blood circulates through an extracorporeal bypass Fibrinogen concentration, antihæmophilic activity, and the platelet-count all fell to about half their normal values However, the prothrombin, estimated by the two-stage area method of Biggs and Douglas,[1] showed a striking initial increase

It may not be sufficiently realised that results obtained by this method are directly comparable only if the fibrinogen concentration and the activity of progressive antithrombin are each identical in the plasma samples tested, Where they differ, corrections must be applied to the results (as area-units observed) before the comparisons are made

Fibrinogen concentration—It is well known that when blood clots, some thrombin is removed by fibrin Hardisty and Pinniger[2] added varying quantities of purified fibrinogen to the plasma of an afibrinogenæmic girl, and found that about half the thrombin liberated was bound by the normal range of fibrinogen concentration and would thus remain undetected in tests on normal plasma Their data show the thrombin area observed to be linearly related to the square-root of the fibrinogen concentration (*w/v*), the observed area fell by 2 2 thrombin mins per root mg % increase in the fibrinogen concentration in the reaction

From the theoretical model discussed below, it may be anticipated that the slope of this regression would vary inversely with antithrombin potency, and it is possible that deficiency or excess of prothrombin might also affect the relationship, and thus further complicate the interpretation of the test Without further investigation, it does not seem possible to calculate the appropriate corrections

Progressive antithrombin—Biggs and Douglas[1] based their area method on the close correspondence between observed two stage curves and a theoretical model derived from consecutive first-order reactions, they were careful to point out the implication that the area under the curve will not provide a measure of prothrombin "unless the level of antithrombin is normal"

Imagine an effectively first-order system containing a *finite* quantity of prothrombin (measured in equivalent thrombin units), a, with thromboplastin and antithrombin, supposedly in excess and therefore constant, denoted by P and A respectively *Then the* concentration of thrombin, y, at time t is given by

$$y = \frac{aK_1}{K_2 - K_1}\,(e^{-K_1 t} - e^{-K_2 t})$$

where $K_1 = k_1P$ and $K_2 = k_2A$, k_1 and k_2 being the reaction constants The area under the curve relating thrombin concentration to time is a/K_2, and is thus inversely proportional to A The relevant measure of antithrombin is not, of course, the total quantity of thrombin which can be destroyed by the plasma in unlimited time,[3] but the rate at which thrombin decays

Therefore, to correct for differences between A_C and A_T (the antithrombin in the control and test plasmas respectively), multiply the test area by K_T/K_C, the observed rates of decay of thrombin added to test and control citrated plasma respectively,[4] which are estimates of K_2 for the two plasmas The decay is exponential, so that log thrombin concentration is *linearly related* to sampling time, and the slope of this line (the fall in log thrombin units per unit time, say K log units per min) is the required measure of antithrombin activity

The position is a little complicated by Seegers'[5] finding that part of the antithrombin activity (antithrombin IV) can be demonstrated only during the conversion of prothrombin to thrombin, and so could remain undetected by this procedure However, we have been able to compare the rates of decay of thrombin added to citrated plasma with and without the concomitant addition of brain extract and calcium chloride, and have not found significant differences. We believe that antithrombin IV may be ignored in determining the two-stage correction

In slowly clotting plasma we have found little change in serial estimates of K The second correction is therefore probably unimportant in the bypass experiments, but the fibrinogen effect should obviously be allowed for since the fibrinogen concentration fell markedly during the period of observation

Dr Wright and others confirmed their anomalous prothrombin results by the acid-precipitated-globulin method[6] Unfortunately, we have found that the "globulin" precipitate also contains fibrinogen (in one experiment, about a quarter of that in the original plasma), so that variations in plasma-fibrinogen concentration may well be reflected in the fibrinogen content of the solution prepared from the precipitate

We therefore feel that the observed increase in prothrombin during slow coagulation is probably more apparent than real, and we would be interested to learn whether the authors feel that it is explicable on the lines we have suggested Of course, we fully accept the main conclusion that slow coagulation was occurring in the bypass

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—I should like to comment briefly on your annotation of June 7

Attrition of the annulus is only one of the results of decreased imbibition pressure in the nucleus, and possibly not the most important one, as hydrostatic effects most certainly occur as well. It seems to me, on the basis of the work to which you refer, unnecessary to postulate a hyperhydration of the nucleus, particularly as this has never in any case to my knowledge been satisfactorily demonstrated, and as the inefficiently functioning nuclear gel will itself produce precisely these effects because it reacts to increased pressure by liberating an abnormally large quantity of fluid It is thus, I think, which is responsible for successive ruptures of the already weakened annulus, and clinically for the acute attacks of pain which are common on the patient's first moving after a period of rest.

The difference between the deterioration of the prolapsed disc and that of the physiological ageing disc is, as you imply in your annotation, a matter for further investigation. I have suggested that the orderly replacement of polysaccharide by collagen in the course of normal ageing could be the factor that prevents hydrostatic effects in the elderly Investigations now being undertaken here by Dr Peter Mitchell suggest that that will in fact prove to be the case Significant changes have also come to light in the content and possibly the composition of the polysaccharide, which we hope to report in due course Indeed, so many variables exist that I cannot share your difficulty in understanding why nuclear desiccation in the elderly should differ from that in the deranged disc. At the risk of perpetrating the inaccuracy that is inherent in all generalisations, one might perhaps say that the difference between normal and pathological ageing is that only the latter will prove to be pathological.

Royal Infirmary,
Aberdeen.
NEIL G C HENDRY

SIR,—In your annotation you quote Hendry's work on the hydration of the prolapsed disc, and go on to say "If desiccation in discs is a major factor in their prolapse, it is difficult to understand why the elderly remain relatively free from major disc derangement" In the article you quote, you will find a plausible explanation

Stresses through the vertebral body are balanced partly by imbibition pressure of the nucleus—the power to retain water which enables cacti to live in the desert and mushrooms to lift paving-stones—and partly by the annulus fibrosus The nucleus consists of a lattice-work of collagen in which is embedded a mucoprotein gel which retains fluid by imbibition pressure In the ageing nucleus the proportion of collagen increases and gel decreases

As the imbibition pressure is reduced, the annulus bears a greater strain, and the character of this strain changes from alternating pressure and tension to a continuous force which may rupture the annulus and allow prolapse of the contained nucleus

As ageing continues, the proportion of collagen rises further Eventually the nucleus is completely fibrosed, and prolapse is virtually impossible

I G MACKENZIE

DEATH OF A BOXER

SIR,—Those of us who were at school nearly half a century ago were told that a sense of proportion was a good thing to acquire and keep

People have been struck on the head by cricket balls and died therefrom One of these, if memory serves, was a Royal Prince. No more cricket?

Necks have been broken playing rugger I had one such in my practice and the patient died. No more rugger?

A tough doctor friend who won the inter-Hospitals boxing at both middle and heavy weight in the same competition played rugger for his university and cricket and tennis for his county, and for many years rode to hounds as if the devil was after him, came to no harm till, in riper years, he took to golf Leaning over to scoop his ball out of a deep bunker he slipped and fell, dislocating his shoulder Clearly, then, no more golf

Meanwhile, of course, let there be no more mountaineering, steeplechasing, or polar exploration all too risky

Most of us, I suppose, die in bed Perhaps we should sit up all night Really, Sir, do we want, or expect, to live for ever?

Crediton, Devon.
L N JACKSON

SIR,—I find it difficult to appreciate the viewpoints of those who maintain that bashing the skull is good for it and those who have to carry out experiments on animals to show that injury to the skull is bad for it Surely the whole design of the skull is such that the structures within it are protected against the normal injuries likely to be encountered in the ordinary rough and tumble of life, but that is no excuse for submitting it to deliberate trauma in the interest of sport

If the general public cannot adopt a common-sense attitude towards boxing and demand its abolition, I suggest that they be asked to treat their skulls with the same respect that they treat their television sets No-one in their right senses would deliberately hit a television set or box its aerials, yet, schoolmasters and parents continue to box children's ears and boxing is still taught as a means of self-defence, although wrestling is safer and more efficient Moreover, as long as boxing is taught in schools and boys' clubs, professional boxing will continue to thrive

At a recent debate on this subject held among patients at the Lancaster Moor Hospital I discussed the subject in this manner and the voting went in favour of boxing being abolished by a small majority One can only hope that they represented a cross-section of the general population

TIME AND THE NERVOUS SYSTEM

SIR,—Thank you for publishing Professor Woodger's definition of an A-line (June 7) I find it difficult to understand why Dr Gooddy (May 31) should think it necessary to explain the well known—such as how a clock works or that joints are of two types (ball-and-socket or hinged)—and unnecessary to explain a difficult concept taken from a discipline different from medicine

He makes some propositions that I am not clear about, such as "There is no system of knowledge about time, to compare with the advanced systems of biology, physics, and chemistry" I wonder is the concept of time comparable with the positive sciences (by which I mean systematised collections of facts) he mentions? Would the assertion "There is no system of knowledge about length or depth to compare with the advanced systems of biology, physics, and chemistry" have any point?

Not everyone would agree with his allegation that the interstate between neurology and psychiatry is neglected, nor that neurology lies at the junctional point of philosophy and science—is there such a junctional point? I cannot see how the neurologist, who may have no training or experience in psychology, psychiatry, semantics, logic, and philosophy can be claimed to be in the best position for the investigation of disorders of the time sense Let me hasten to state I know several neurologists who seem to me to have a knowledge of these disciplines but as far as I can see they acquired it in spite of their training in neurology

It may be that rhythmic activity of the nervous system is related to time appreciation The electroencephalograph demonstrates such rhythmic activity but surely it does not prove any connection with time appreciation On the contrary, alpha rhythm "which shows final abstraction from all other rhythms" disappears with visual activity but time appreciation continues

Shenley Hospital,
near St Albans RUSSELL BARTON

THE CERVICAL AORTIC KNUCKLE

SIR,—In April, 1953, two of us reported[1] the case of a young man whom we had observed periodically since we first saw him, at five years of age, with a pulsating swelling in the right side of his neck, extending as high as the hyoid bone Exploration at that time suggested that it was the arch of the aorta following a second exposure a few months later the overlying deep cervical fascia was reinforced with fascia lata taken from the patient

In 1953 it was noted that, since the operations thirteen years before, there had been no great change in the cervical aortic knuckle, which bothered him slightly if at all he had been regular in attendance at his work as a storekeeper and had had no serious illnesses In March, 1957, he was readmitted complaining of some difficulty in swallowing certain foods, such as potatoes and meat The dysphagia had been present for about six months and was increasing A vascular ring compressing the œsophagus was suspected and the evidence obtained by angiography supported this

On April 2, 1957, left posterolateral thoracotomy through the bed of the fifth rib (H R S H) confirmed the diagnosis The transverse retro-œsophageal segment of the aorta, the ligamentum arteriosum, and the right and left pulmonary arteries formed a vascular ring which fitted tightly around the trachea and œsophagus, the posterior wall of which was indented by it The ligamentum arteriosum was tense, nearly an inch in length, and formed the left part of the ring extending from the left subclavian artery at its junction with the aorta to the left pulmonary artery at its junction with the right branch After division of the ligament the constriction of the trachea and œsophagus was relieved and his dysphagia alleviated He remains well and free from symptoms a year later

In our first report of this case we drew attention to the condition of cervical aortic knuckle in a child Recognition of its nature is important since it has been mistaken for an aneurysm and operated upon with fatal result. We have presented this further note because, in cases of abnormality of the aortic arch, *it would seem reasonable to* suspect the presence of an intrathoracic vascular ring which, by encircling the trachea and œsophagus, may in the course of time cause dysphagia

A detailed discussion on the embryology of these cases will appear in an article by one of us (H R S H) shortly to be published in the *British Journal of Surgery*

Parliament

Proposed Amendment of Registration Procedure

ON June 11, under the ten-minute rule, Mr JOHN HYND, a former member of the General Medical Council, asked and obtained leave to introduce a Bill to amend the Medical Act of 1956 The wording of that Act, Mr Hynd said, had proved anomalous and the procedure it laid down cumbersome The amendments proposed in his Bill would affect two groups of doctors those who had qualified in this country before Jan 1, 1953, but who for some reason had not applied for registration, and those who qualified in this country because they held foreign or Commonwealth diplomas not recognised for registration Both these groups, irrespective of their previous experience, had still to do twelve months' internship in a hospital before they could obtain full registration His Bill would put these groups on the same footing as doctors with Irish or recognised foreign qualifications who could obtain full registration if they offered evidence of appropriate hospital experience

Mr Hynd's Bill would also simplify the administrative procedure for admitting doctors to the provisional register At present they had to produce a certificate of selection for employment and their qualifications had to be checked by the hospital and counterchecked by the board This often meant considerable delay, and as a result doctors might be practising for days or weeks in hospitals quite illegally before they had been formally admitted to the Provisional Register He suggested that we should return to the earlier procedure which left authority in the hands of the G M C

Mr Hynd assured the House that these changes had been discussed with the G M C, the British Medical Association, and other bodies who had all agreed that they were not only necessary but desirable

Princess Louise (Kensington) Hospital for Children

In the House of Lords on June 16, Lord STRATHCLYDE, replying for the Government to a question about the future of this hospital,[1] said that the Minister of Health had decided to approve the temporary use of two wards for maternity patients during adaptation of the maternity unit at St Mary's Hospital He could not approve the long-term use of the hospital for adults, but would review its future again towards the end of the period of temporary use, which would be about two years after adaptation had been completed

QUESTION TIME

A New Regional Hospital Board

Mr JOHN EDEN asked the Minister of Health if he had yet come to a decision as to the date on which it would be possible to set up a separate Wessex Regional Hospital Board for the

---

[1] See *Lancet*, 1957, ii, 41

South West Metropolitan Region —Mr DEREK WALKER-SMITH replied I have decided that it will be possible to do so on April 1 next and I am taking the necessary steps to bring the new region and regional hospital board into being on that date

Morphine and Heroin Addiction Committee, 1926 (Review)

The Minister of Health, in consultation with the Secretary of State for the Home Department and the Secretary of State for Scotland, has appointed a committee with the following terms of reference

To review in the light of more recent developments the advice given by the Departmental Committee on Morphine and Heroin Addiction in 1926, to consider whether any revised advice should also cover other drugs liable to produce addiction or to be habit-forming, to consider whether there is a medical need to provide special, including institutional, treatment outside the resources already available, for persons addicted to drugs, and to make recommendations, including proposals for any administrative measures that seem expedient

The membership of the committee is as follows

Sir Russell Brain, F R C P (chairman), Laurence Abel, F R C S, D M Dunlop, F R C P, Donald W Hudson, M P S, A D Macdonald, M D, A H Macklin, M D, S Noy Scott, M R C S, and M A Partridge, D M

Emergency Telephone Lines for Hospitals

Mr HERBERT MORRISON asked the Minister whether he had considered the report on emergency telephone and other arrangements at Lewisham Hospital in connection with the Southern Region railway disaster at St Johns, and what action was being taken —Mr WALKER-SMITH In general the arrangements appear to have worked well, and I should like to take this opportunity of paying a tribute to all who took part in meeting a very difficult situation Detailed points have been discussed by representatives of the services concerned, and steps have been taken in this region to arrange for ex-directory lines at major hospitals and for a review of their telephone communications The report has been circulated to all regional hospital boards, and consideration is being given to certain matters by my officers with a view to further action if required

Hospitals Staffing Working Party

Mr KENNETH ROBINSON asked the Minister the terms of reference of the working party set up to consider the medical staffing structure of the hospitals —Mr WALKER-SMITH replied To study, in the light of experience of the hospital service since 1948 and of all other relevant considerations, the principles on which the medical staffing structure in the hospital service should be organised Mr ROBINSON What member of the Working Party is qualified to assess the special needs of the mental hospitals in relation to medical staffing, and whether, in view of the composition of the working party, it is the Minister's intention to exclude from their consideration the problem of mental hospital staffing —Mr WALKER-SMITH As the terms of reference indicate, the working party is to study the principles on which the medical staffing structure should be organised and not the number of staff required by individual hospitals The working party is well equipped to cover the hospital service generally and I see no reason to modify its terms of reference

Private Beds in London Hospitals

Mr HENRY HYND asked the Minister of Health how many private beds were now available in London hospitals, as compared with the number before the creation of the National Health Service —Mr WALKER-SMITH replied At Dec 31, 1957, 2255 beds were available under sections 4 and 5 of the National Health Service Act, 1946, in the Metropolitan Police District I understand that there were 2288 beds classed as private beds in the same hospitals shortly before the inception of the National Health Service, but as there was then no accepted definition of the term " private ", the figures are not strictly comparable.

Poliomyelitis Vaccine

In answer to a question Mr WALKER-SMITH said that by April 30 over 3 million persons in Great Britain had been vaccinated with two injections, just over $2^{1}/_{2}$ million were awaiting vaccination, and a further 500,000 were awaiting their second injection On that date the local health authorities held 1 million doses of vaccine and they had since received over 5 million more This was more than sufficient to complete the vaccination with two doses of all persons registered by April 30 if they were willing to accept the type of vaccine available Further supplies of vaccine were being distributed from time to time to keep pace with new registrations He could not at present make any statement in regard to extending the offer of vaccination to other priority groups or about the giving of third doses

---

Obituary

JOHN CLARK MIDDLETON

M A, M B, B Sc Glasg, F R F P S

Dr J C Middleton, honorary consulting physician to Glasgow Royal Infirmary, who died on May 30, will long be remembered as one of the characters of the Glasgow medical school His students respected his gift for clinical teaching and his colleagues his flair for diagnosis As one of them has said, " he was terse, sometimes uncomplimentary, but always helpful "

He was born in Glasgow in 1883, the son of a schoolmaster, and educated at Whitehill School and Glasgow University He graduated M B with honours in 1907 and after holding house-appointments in Glasgow hospitals he spent several years in general practice and acted as assistant bacteriologist to the burgh of Partick In 1910 he was awarded the McCunn research scholarship and joined the staff of the university department of materia medica, where he worked under Prof Ralph Stockman In this appointment he undertook a great deal of pharmacological research and was responsible for the smooth running of the experiments undertaken by student volunteers During the 1914–18 war he served with the R A M C After he was demobilised he returned to clinical medicine and became assistant physician to the Glasgow Royal Infirmary and visiting physician to the Western Dispensary He also held a university lectureship in pharmacology and later in clinical medicine In 1926 he was appointed chief in charge of wards at the Royal Infirmary, and he held this post until he retired in 1948

A H I, who was on Middleton's staff in the 'thirties, writes

J C Middleton was burly and rubicund with very little hair, his manner was bluff with a rather mordant wit, and his language at times was distinctly salty Indeed, he was more like a prosperous farmer or ship's captain than a successful consultant physician He had a reputation for lightning diagnosis, usually made from the foot of the patient's bed Naturally he was sometimes wrong, but the frequency with which he was right was no surprise to those of us who knew his powers of acute and shrewd observation and his phenomenally retentive memory He loved controversy and even appreciated being flatly contradicted A ward round with him was a stimulating experience Afterwards he would adjourn with his staff and over coffee would light one of the pipes of which he carried at least four ready charged Amid clouds of acrid smoke, strongly tinctured with thick black tobacco, he would converse or argue on any topic under the sun His assistants and house-physicians held him in such high esteem that they founded the J C M Club whose sole function was to entertain him to dinner once a year Former residents used to assemble from far afield and he was always at his best on these occasions He has been retired for many years, but his memory is still vividly alive in his old hospital, and his passing will sadden all those of us who worked with him and knew him

GEORGE HERBERT GARLICK

M R C S, D M R E

Dr G H Garlick, director of the Anti-Tuberculosis Association Clinic, Singapore, died in Switzerland on June 6 while on his way to London to attend a conference

He was born in 1886, the son of Dr George Garlick, of Gordon Square, London He was educated at Epsom College, and studied medicine at St Mary's Hospital, qualifying in 1912 Two years later he went to Malaya, first as medical officer to a tin mine for two years and then as medical officer to the Johore Government He was appointed principal medical officer in 1930 Before he retired in 1941 he was largely responsible for designing the great new hospital at Johore Bahru He retired to a cylindrical house he had built in the outskirts of Singapore, but almost at once joined the R A M C as specialist in radiology He became a prisoner-of-war of the Japanese After the war he returned to live at the Round House, Garlick Avenue, and applied his knowledge of radiology to the campaign against tuberculosis He was a prime mover in the Anti-Tuberculosis Association, and when the Singapore clinic was opened in 1952 he became the director He married Myrtle H W I Ventris, by whom he had two daughters and a son, who is in general practice at Lakenheath in Suffolk

J K M writes

Dr Garlick will be remembered especially for his complete absence of snobbery and race-prejudice and by the Johore Bahru Hospital His house was decorated by Chinese objets d'art There was a bathing-pool beside which were tropical flowers and a life-size statue of a woman balancing on her hands Gracious and modest, he was a charming host and colleague

Notes and News

NURSES' HOURS OF DUTY

THE Minister of Health has accepted (H M [58] 45) a recommendation by the Nurses and Midwives Whitley Council that the hours of duty of hospital nurses and midwives (excluding staff in supervisory posts) should be reduced from 96 to 88 per fortnight as soon as conditions permit, and he has asked hospital boards and committees " to put in hand forthwith a complete review of the existing nursing and midwifery services and staffing arrangements in their hospitals with the object of giving effect to the recommendation to the fullest extent which local circumstances make practicable " Any increase in expenditure will have to be met by hospital authorities within the total of their authorised budget and additional funds will not be made available The Minister recognises that this may limit the extent to which boards and committees will find it possible to implement the recommendation, but he feels sure that " a good deal can be done by concerted administrative action to reduce the hours of duty of nurses and midwives below the level worked at present " The Minister hopes that boards and committees will give special attention to the work of student nurses, and try to eliminate or reduce split duties wherever possible, and to arrange that the staff as a whole plan their off-duty time well in advance

WORLD HEALTH ASSEMBLY

AT the World Health Assembly, in Minneapolis, Minnesota,[1] the W H O Committee on Programme and Budget approved the 1959 general programme of work, which reflects increased activities against malaria, venereal diseases, treponematoses, and endemo-epidemic diseases, and in public-health administration, nursing, maternal and child health, mental health, and nutrition Several delegates spoke of the need to expand and improve health statistics The committee unanimously approved a proposal sponsored by the U S A requesting the Director-General to " organise and arrange for special study of the role of the Organisation in research, and ways in which W H O might assist more adequately in stimulating and coordinating research and developing research personnel "

EXTRAMURAL MEALS

MOST of us look forward to our meals with zest, and to the patient in hospital they are often the main events of his rather dull day and a vital part of his treatment The importance of serving him with appetising, hot, nutritious meals is clear to all hospital administrators, so, too often, is the difficulty In some hospitals, especially our large mental hospitals,[2] the kitchens are saddled with antique equipment and lie at a chilling trolley ride from the outlying wards The food is cooked in bulk and much of it is at least partially prepared the day before it is eaten All these defects are often aggravated by shortage of staff But boards, management committees, and hospital officers alike are alert to make the best use of their resources, and most patients would agree that hospital food is improving

A possible innovation which is being considered by the Battersea and Putney Group H M C, at the suggestion of the South West Metropolitan R H B, is to entrust the catering to an outside industrial firm A firm, Peter Merchant Ltd, which are responsible for the catering of some hospitals in Northern Ireland and of Army units at Didcot, have visited two of the hospitals of the group (St John's Hospital, a long-stay hospital of 469 beds, and Putney Hospital, an acute hospital of 106 beds) and submitted reports on their catering and the terms on which the firm would be willing to take it over

If the scheme is accepted the firm, acting through supervisory executives visiting regularly, would instruct the catering staff in their methods of kitchen control, menu planning, and cooking, and generally supervise the department In this way they would act as the hospital's catering officer They would buy on the open market, using their national buying power and taking advantage of market fluctuations They would, therefore, need to have control of the food stores and would install a control-clerk/storekeeper This would be the only employee engaged by them to work wholetime at the hospital The rest of the staff would remain the employees of the H M C The firm would be paid an agreed annual fee for this work and would also be reimbursed for the cost of food consumed in the hospital

---

[1] See *Lancet*, June 7, 1958, p 1234, *ibid* June 14, p 1286

[2] Hawes, D G H *Lancet*, 1955, i, 1214

Battersea and Putney H M C are at present studying the survey submitted by the firm, and it is hoped to make a decision shortly whether to allow the firm to take over the catering for an experimental period of not less than 6 months The objects of the experiment would be, first in importance, to test the firm's claim that, as specialists, they would be able to improve the standard of catering for the benefit of patients and staff alike, and, second, to save money if possible

GERIATRIC REABLEMENT UNIT

On May 28 Lady Wakehurst opened a new wing at the Belfast City Hospital which is to serve as an extension of the department for the care of the elderly sick

Wakehurst House, as it is to be called, has evolved from ten years' experience of the reablement of the elderly sick, and it has been specially planned for this work. Two unusual points in the design are the exercise bays and the sections for long-stay invalids On the ground-floor there are staff offices and outpatient services, including physiotherapy and occupational therapy The first and second floors have male and female 41-bed ward units respectively The ward units were planned in the belief that sooner or later all doctors and nurses must accept responsibility for some long-stay patients so as to spread the load and avoid the unhappy concentrations of chronic sick of the old days Each unit is L-shaped, the short limb is a separate 16-bed annexe with its own services, including lavatories, bath, sluice, and enema rooms, for long-stay invalids who need continuous nursing care The long limb of the L is a 25-bed reablement ward divided into four open 6-bed cubicles and one single-bed ward for critically ill or disturbed and restless patients To one side is a wide bay giving space for parallel bars, walking chair, and other facilities for daily exercise At the ward entrance is a pleasant day-space close to the kitchen at the base of the L, and there is a sun balcony wide enough to take several beds

Dr William Blackwood has been appointed to the university chair of neuropathology at the Institute of Neurology

Dr Blackwood, who is 47 years of age, qualified from the University of Edinburgh in 1934 After filling house-appointments in Edinburgh at the Royal Infirmary and the Royal Hospital for Sick Children and at Inverness he became assistant pathologist at the Royal Infirmary and was awarded the Crighton research scholarship In 1938 he took the F R C.S E and in 1957 the M R C P.E In 1939 he was appointed pathologist to the Scottish Mental Hospitals' Laboratory and neuropathologist to the Royal Infirmary and Municipal Hospitals, Edinburgh In 1945 he was appointed senior lecturer in neuropathology in the University of Edinburgh In 1947 he came to London to join the staff of the National Hospital, Queen Square, as assistant pathologist, later becoming pathologist His published work includes papers on immersion foot and on diffuse cerebral sclerosis He was one of the authors of *Atlas of Neuropathology* which was published in 1949 and of the late Dr J G Greenfield's *Neuropathology* published earlier this year

Dr J N Cumings has been appointed to the university chair of chemical pathology at the Institute

Dr Cumings, who qualified from King's College Hospital in 1927, is 52 years of age After holding house-appointments at King's, he became assistant pathologist there In 1930 he took the M R C P and a year later the M D Lond In 1933 he was appointed assistant pathologist, and in 1945 clinical pathologist to the National Hospital, Queen Square He was elected F R C P in 1953 He has published papers on creatine metabolism, on hepatolenticular degeneration, and on cerebral lipids in various diseases

Dr N F Morris has been appointed to the university chair of obstetrics and gynæcology at Charing Cross Hospital Medical School

Dr N F Morris is 38 years of age and qualified from St Mary's Hospital in 1943 After holding resident appointments at St Mary's and the East Ham Memorial Hospital he joined the R A F, in which he served as a surgical specialist with the rank of squadron-leader In 1948 he returned to a registrar appointment at St Mary's and also at the East End Maternity Hospital, and in 1949 took the M D Lond and the M R.C O G Later he became senior registrar in the department of obstetrics and gynæcology, Hammersmith Hospital, where he remained until 1953 when he was appointed first assistant in the obstetrical unit at University College Hospital He took up his present post of reader in obstetrics and gynæcology at the Institute of Obstetrics and Gynæcology and consultant obstetrician and gynæcologist to Hammersmith Hospital in 1956 He has published papers on several obstetric subjects His recent studies have concerned the use of radioactive isotopes in the assessment of the effective uterine blood-flow at rest in late pregnancy and during exercise, and also during labour

Royal College of Obstetricians and Gynæcologists

On Friday, July 25, at 5 P M, at the college, Prof James Black, formerly of the University of Witwatersrand, will give the William Meredith Fletcher Shaw lecture The title of his lecture is Reminiscences of Fifty Years' Medical Practice—forty-seven of them in South Africa Tickets may be had from the secretary, 58, Queen Anne Street, London, W 1

Royal Australasian College of Physicians

At a meeting of the general body of fellows of the college held in Sydney on June 4, the following were elected and admitted to fellowship

Under article 44 Lionel Lockwood (Victoria), J A R Miles (New Zealand), J S Robertson (South Australia) *Under article 42* R A Bakewell, J D Bergin, R C S Dick, W G Gray, G P Hallwright, J A Keeling, L S A Lewis, R W Medlicott, C P Powles (New Zealand), R B Blacket, Clair Isbister, A G McManus, R D Puflett, D S Stuckey, Helen M Taylor (New South Wales) Joseph Bornstein, H N B Wettenhall (Victoria) J V Gordon, B S Hetzel (South Australia), G B V Murphy, N V Youngman (Queensland)

On June 3 the following were admitted to membership

R J Cantwell, T P Casey, R J M Coates, C O Crawford, P M Dennis F E Dreifuss, J D Frankish, Colleen A Hall, E E Hannah, H J H Hiddlestone, R O H Irvine, Dr Malcolm Watt (New Zealand), L Bernstein, R W Boden, G M Bourke, B S Clifton, H Kronenberg, L Lazarus, M A Mishkel, J G Opie W K A Paver, June M Raine F L Ritchie, W A Seldon, K A Talley, W H Wolfenden (New South Wales), R R Andrew P F Bladin, D M Danks, A P Dorevitch, J A Game, G S Hale, A D McCutcheon, F I R Martin, S Shub (Victoria), T H Beare, J R. Lawrence, R H C Rischbieth (South Australia), J M Sutherland (Queensland), B C Bignold (Western Australia) *Under article 37* M C Fowler (South Australia), R D K Reye (New South Wales)

Royal College of Surgeons of England

On June 11 a ceremony of presentation of diplomas was held, for the first time, at the college

Prof C F W Illingworth (Glasgow) and Prof F de G d'Allaines (Paris) were admitted to the honorary fellowship Prof R W Scarff, Air Vice-Marshal J C Neely, and Prof F C Wilkinson, who had been elected fellows, were formally admitted

The presentation of diplomas to those who had been successful in the examinations of the college during the past year followed Parties from each of the medical schools were presented in turn to the president for receipt of the diplomas at his hands, and some 200 diplomates were presented in this way

At a meeting of the Council on June 12, with Sir James Paterson Ross, the president, in the chair, the following were coopted to the council for the year 1958–59, representing various branches of practice

Dr John Hunt, general practice, Dr Frankis Evans, anæsthetics, Mr T Keith Lyle, ophthalmology, Mr A C H Bell, gynæcology and obstetrics, Prof D W Smithers, radiology, Mr C Gill-Carey, otolaryngology, Sir Wilfred Fish, dental surgery

Mr D Ioan-Jones and Mr T G I James were re-elected members of the court of examiners for a further three years

The Hallett prize was awarded to Miss M V Ramchandani of the University of Bombay

Diplomas of fellowship were granted to the following

G B Northcroft, Valerie M Thompson, W B Ashby, R S Sneath, F R Coffin, A E Buckle, P L C Diggory, Alan Gillespie, F J Moynihan, J M Powley, W J Pryn, D M Millar, K R Pool, R Y Calne, A R Bearn, Richard James, P S Boulter, George Hayes, John Mutch, I K Mikhail, A K Chowdhury, William Lees, K A McCluskey, K A Menon, Joan Fowler-Wright, Hilton Harrop-Griffiths, N H Harris, R H Lewis, A H Petty, Kenneth Bloor, H G Brown, T I El-Gailani, Joseph Magri, G A W Milner, R F Rohan D S Sardana, C B Walker K R Alimchandani, D S Dharmage, J L Dowse, J G Gray, G L Grigg, A C Jain, K N Khanna, M L Rajakaruna, Veluppillai Rasanayakam, G E Rousseaux, E J Williams, J A Adams, S D Chatterjee, M H Cox, J C Currie, E J England, A P Fuller, B E Hagan, A H T Hodgkinson, R A Howett, Isidore Kaplan, B H Kelham, H M Learoyd, C V Mann, J A Marston, V G Mavalankar, John Moran, D C Patel, G C Robin, I B Tait, L J Walker, J H Williams, Raphael Attard, Dudley Churchill-Davidson, J A Girling, P B Humphris S R Mitra, S K Nair, B T O'Connor, K C Perry, W D Proudman, G R Raad, M P Robinson, J F Sander, Lucas Souvlis, H H Srinivasan, Prem Virmani, N K Yong, Lakshman Das, H F Jeejeebhoy, I D Johnston, M Y D Koawavwala, M G Maguire B A Maurice, D O Sullivan, C G Paull, J G Ross, S B Singh, J R Solomon, D E Cam, R D P Craig, A R Desai, K H Langford, M B Menelaus, R P Silverton, R G Smith, J L Dawson

Lady Tata Memorial Fund

For research on leukæmia and allied diseases in the year beginning October, the trustees have made the following awards

Grants for Research Expenses —Dr M Seligmann (France), Dr M Simonsen (Denmark), Prof B Thorell (Sweden), Dr M Bessis (France), Prof G Klein (Sweden), and Dr Jan Ponten (Sweden)

Scholarships —Dr A J Therkelsen (Denmark), and Dr Aiyappan Pillai (Switzerland)

N H S Administrative and Clerical Staffs

The two sides of the Administrative and Clerical Staffs Whitley Council have agreed that as a preliminary to negotiations on the application of the Noel Hall report to senior designated grades, an independent fact-finding committee of three should be asked to report on current rates of remuneration of staffs employed on comparable work in other employment Sir Noel Hall has accepted an invitation to serve as chairman of the committee

Institute for Advancement of Medical Communication

This institute was recently formed in New York "to study and develop ways to increase the efficiency of information exchange among medical scientists, medical educators, and practising physicians" The work of the institute, which is a non-profit organisation, will be financed by grants from private foundations and from agencies, private and federal, which support medical research The charter members of the board of directors are Dr Chauncey D Leake, professor of pharmacology, Ohio State University, Dr Homer W Smith, professor of physiology, New York University, and Dr Irving S Wright, professor of clinical medicine, Cornell University Dr Richard H Orr, assistant editor of *Metabolism* and formerly medical director of Grune and Stratton, Inc, will serve as executive director The temporary headquarters of the institute are at 37, East 67th Street, New York 21, N Y

Symposium on Clinical Endocrinology

This symposium, limited to 30 consultant physicians, will be held from July 7 to 11 at the Postgraduate Medical School of London, Ducane Road, W 12 Further particulars may be had from the dean

Diamond Jubilee of the R A M C

On Wednesday, June 25, at 5 P M, at B M A House, London, W C 1, Sir Gordon Gordon-Taylor will give an oration, entitled *In Arduis Fidelis*, to commemorate the diamond jubilee of the R A M C

Snow Centenary

On June 16, the centenary of the death of John Snow, wreaths were laid on his grave in Brompton Cemetery by the president and members of the council of the Association of Anæsthetists of Great Britain and Ireland, the dean of the Faculty of Anæsthetists of the Royal College of Surgeons of England, and the presidents of the Sections of Anæsthetics and Epidemiology of the Royal Society of Medicine

The honorary degree of doctor in the faculty of science of the University of Bologna has been conferred on Sir Charles Dodds The British Ambassador attended the ceremony and the new graduate afterwards gave an address in French

The Oliver Bird Prize for 1957 has been awarded to Dr Gregory Pincus of the Worcester Foundation for Experimental Biology, Massachusetts

The Bárány jubilee medal of the University of Uppsala has been awarded to Dr C S Hallpike

The council of the Middlesex Hospital Medical School have given the Comfort Crookshank award for cancer research for 1957 to Prof Charles Huggins of the University of Chicago He will deliver a lecture at the school at 3 30 P M on Thursday, July 3, on cancer of the prostate

A meeting of the Biochemical Society will be held in the department of biochemistry of the University of Sheffield, at 2 P M on Friday, July 18

The North Western Tuberculosis Society has adopted a new constitution and altered its name to the North Western Thoracic Society

The annual general meeting and dinner of the Cambridge Graduates' Medical Club will be held at Gonville and Caius College on Friday, July 4, at 7 45 P M The Master of Gonville and Caius and the Regius Professor of Physic are dining as guests of the club Any members who have not received notice of the dinner should write to Dr T B Anderson, 1, Huntingdon Road, Cambridge

The British Standards Institution has issued a draft British standard for hospital sterilisers horizontal cylindrical steam pressure type (CY [SGC] 5522) Comments should reach the Institution, British Standards House, 2, Park Street, London, W 1, by July 4

Appointments

EASTON, A L T, M B Cantab, F R C S, M R C O G consultant obstetric and gynæcological surgeon, London Hospital

GRATTON, ANNIE R, M B Manc. school M O and assistant M O H, Middlesbrough

HIGGIE, C B, M R C S, D P H M O H, Ellesmere, Wem, and Whitchurch, and assistant county M O, Salop

MACGREGOR, G A, M D Lond, M R C P part-time consultant physician, Guildford group of hospitals

MACLEOD, R C, M D Glasg, D P H, D T M & H Sidmouth, Ottery St Mary, Axminster, Seaton, and Honiton

VAUGHAN, G F, M B Lond, M R C.P, D P M physician in child psychiatry, *Guy's Hospital, London*

Colonial Appointments

BINNS, T P, M R C S, D P H principal M O (urban health), Northern Nigeria

BOULOUX, J A F, M R C S, D L O specialist (E N T diseases), Mauritius

DIKKO, R A B, M R.C S principal M O (endemic diseases), Northern Nigeria

LOU-HING, E W, L R C P E superintendent M O (specialist), leprosarium, Chacachacare, Trinidad

LYDON, DANIEL, M B N U I senior administrative M O, Northern Nigeria

SEXTON, J P, M B Edin, D P H, D T M & H principal M O (curative services), Northern Nigeria

SHUN SHIN, MAXIME, M B Lond, D T M & H medical superintendent, Mauritius

The Lancet · Saturday 28 June 1958

THE PLACE OF THE RESEARCH INSTITUTE IN THE ADVANCE OF MEDICINE *

Sir Charles Harington
Sc D Cantab , F.R S
DIRECTOR OF THE NATIONAL INSTITUTE FOR MEDICAL RESEARCH, LONDON, N W 7

A scientist of the present day who is prepared to extend his thought beyond the range of his own activities, or even his own subject, to such matters as the general impact of scientific work on civilised human life will be likely to find himself with mixed feelings On the one hand he will be filled with pride in the achievements of science and the benefits that its applications have brought, on the other he will feel some qualms about the attendant dangers The dangers that I am thinking of are not the obvious risks of misuse of scientific potential for destructive purposes, but the more subtle dangers that are inherent in the undue dominance of any particular intellectual discipline over the trend of human thought

As the achievements of science become more striking and as their impact on the practical affairs of daily life become more manifest, it is inevitable that a feeling should develop that the powers of science are limitless Such a misconception is likely of course to prevail mostly among those who are uninstructed in science, but in so far as it exists it is bound also to have some effect on scientists themselves For both the result will be harmful the scientists will tend to lose that degree of intellectual humility which is necessary for sincere scientific effort, whilst, for the non-scientific, science will become invested with an aura of mystery that might in the end confer on it a dominance over thought as restrictive as any of the religious systems have been in the past

The avoidance of such a state of affairs must depend on an increasing knowledge of science on the part of those not actually engaged in its pursuit Only from such a dissemination of knowledge can come a rational view of science which will dispel mystique and bring about a general appreciation not only of the powers of science but of its limitations, together with a recognition of what scientific work has become today—namely, one of the learned professions

These remarks may seem to be as obvious as their relevance to my present theme is obscure The point that I am particularly seeking to emphasise, however, is the importance of recognising the extent to which scientific work of all kinds has become professionalised For all professions imply organisation, and it is one aspect of organisation in one branch of scientific work that I have undertaken to discuss

Organisation and Restraint

There will be many people who will feel some reluctance to admit the necessity of organisation for scientific work, particularly so far as basic research is concerned Whilst there can be no denial of the necessity for a high degree of organisation in scientific industry and in what is commonly regarded as applied and development research, it may well be felt that original investigation must remain a purely individual intellectual activity that can only be properly pursued in conditions of complete freedom, inconsistent with any form of organisation

Though it is still true that there are some people of rare intellectual quality who are so irked by all forms of restraint that they can produce their best efforts only when their thoughts are untrammelled by any considerations other than the pursuit of knowledge, these are in my opinion very few in number The feeling to which I have referred is based I believe on a nostalgia for the time when the body of scientific knowledge was such that one branch at least could be fully comprehended by an individual, when techniques were simple and when the practical applications of scientific research were less urgently sought after This time is past beyond recall, as scientists we are no more entitled than anyone else to eat our cake and have it, and if we desire our profession to make its proper contribution to civilisation we must accept the conditions imposed by the more highly organised society in which we have to live

A further consideration is that as time goes on the importance of the work of any one person in the total scientific effort inevitably becomes less The reasons for this change are obvious As the body of scientific knowledge grows the portion that can fall within the comprehension of any one man becomes less, and even within the field that he himself has mastered his efforts will be more and more conditioned by the work of those who have preceded him This may sound like a denial of the importance of originality, it is, of course, far from being so there can never be enough originality, but with the passage of time evidence of originality is more likely to be found in the perception of hitherto unobserved correlations of knowledge than in the conception of entirely new ideas

If it be accepted that the profession of science cannot dispense with an organisation there remains much room for discussion as to the type of organisation best suited to its particular requirements It is evident at once that, especially when we come to consider original investigation, the question is not easy to answer, for in respect of this particular type of scientific activity—and it is the activity on which in the last analysis all else depends—what we have to seek is an organisation that combines the two apparently opposing characteristics of high efficiency and minimum restraint The fact that this opposition exists is inherent in the present state of development of human beings who can still not work together efficiently in the absence of some measure of control, the less such control is imposed by authority and the more it can be replaced by the willing acceptance, if not the self-imposition, of a system of organisation the better, it seems to me that this consideration should be constantly in the minds of those whose duty it is to try to organise scientific work After all, anarchy is not synonymous with chaos, and however unrealistic the conception may at present be there could be worse ideals for the scientific profession, and indeed other professions dependent on the free play of intellect, than the ultimate approximation to a system in which order coexists with anarchy

However, such flights of fancy are ill suited to the servant of a Government organisation, and in any case the situation that faces us now and will face us for many years to come has to be considered on a practical basis

---

* The Linacre lecture, delivered in the University of Cambridge on May 6, 1958

The Roots of Medical Research

So far I have spoken of scientific research in general, I now wish to narrow the discussion to the field of medical research as practised today and as likely to develop in the future Such a restriction does not imply any essential difference between medical research and other forms of scientific investigation, the advance of all forms depends on a sincere desire for increasing knowledge It is platitudinous nowadays to remark that in medical research the new light may come at the one end of the scale from laboratory studies of an apparently academic character and at the other from observation at the bedside The motivation of the medical research-worker may indeed be more complex than that of other scientists, because few even of those who work only in laboratories are not influenced from time to time by the thought that their efforts are ultimately directed to the prevention and cure of illness The emotional factor thus introduced may clearly work for good or ill it is good in so far as it inspires enthusiasm and gives direction to a man's efforts, and bad in that it may remove objectivity and lead to undue haste for practical results

So far as this country is concerned, medical research, like other forms of original scientific work, has its roots in the universities, if this term is understood to include the great centres of clinical teaching, and if we think of the outstanding medical men of the past who have made major discoveries as practising clinicians we have no reason to belittle the contribution that has come from this source It is quite vital to the intellectual life of any country that the universities should retain the place that they have hitherto occupied in the vanguard of thought, and in science this means not only inspiration in teaching but also activity in investigation, no-one is likely to dispute this, but differences of opinion may arise on the extent to which basic research in medicine should be pursued outside universities and medical schools Assuming what is indeed a self-evident fact, that without very great expansion of their resources the universities could not attempt to cover the whole field of basic research in medicine or indeed in any other scientific subject, is it better to extend university resources or to make independent provision of a different character?

The First Institute for Medical Research

The conviction that something more than the universities and medical schools was in fact needed for the advance of medical science took root in the minds of some a considerable time ago, and found expression in the establishment of such institutions as the Koch and Pasteur Institutes and our own Lister Institute These institutions, however, although broadening the basis of their work as time went on, were set up in the first instance with somewhat closely defined terms of reference, chiefly related to prevention and treatment of infective disease by inoculation, the first Institute for Medical Research founded for the development of basic research without any restriction on its field of activity was the Rockefeller Institute, and it is relevant to our theme to consider the circumstances that led to its establishment

The story of these circumstances has been told in the life of John D Rockefeller, Jr , published a year or two ago by Raymond B Fosdick, and it reveals a surprising fact—namely, that the notion of a general institute for medical research was first put forward by a man who was neither a doctor nor a scientist It was that astonishing individual Frederick T Gates, once a Baptist minister, later adviser in business and in philanthropy to the elder Rockefeller, and a man who profoundly influenced John D Rockefeller, Jr , who conceived the idea, and devoted all his missionary fervour to obtaining its acceptance

When Gates was seeking for ideas to suggest to Mr Rockefeller senior for the distribution of his rapidly increasing fortune he happened to read Osler's *Principles and Practice of Medicine* He records his enjoyment in reading the work, which he describes as one of the few scientific books possessed of literary attraction. In spite of the æsthetic satisfaction that he derived from his perusal, however, Gates was left at the end with a sense of disillusionment, if this book were the best presentation that could be made of medicine, how backward must be the scientific study of the subject, particularly in the United States at that period

Convinced that something was urgently needed to remedy this state of affairs, and recalling the success in their limited fields already achieved by the Koch Institute in Berlin and the Pasteur Institute in Paris, Gates submitted a memorandum to John D Rockefeller proposing that the latter should set up an institute for medical research No suggestion was made that the activities of the institute should be restricted to any definite lines, indeed the breadth of Gates' conception was surprising for a man with no knowledge of scientific work, as is shown by the key sentence of his memorandum " Medicine can hardly hope to become a science until it can be endowed, and qualified men enabled to give themselves to uninterrupted study and investigation, on ample salary, entirely independent of practice " This was written in 1897

Since the Rockefeller Institute was to afford the first demonstration of the role that such an organisation could play in medical research, it was well that the underlying idea of its establishment was so liberal, it was even more fortunate that the medical scientists, in particular William H Welch, who were consulted about the practical implementation of Gates' ideas were themselves men of wide vision who had the authority to insist that the work of the institute must be kept on a broad scientific basis, and must by no means be regarded as aiming at quick practical results immediately applicable to medical treatment There can be no doubt that faithful adherence to this conception of the purpose of the organisation was responsible for the great scientific reputation that it quickly built up and has since maintained

This is not the occasion for a discussion of the achievements in medical science for which workers at the Rockefeller Institute have been responsible These are matters of world repute, but for the purposes of the present argument their significance lies in the demonstration they afford that, at least in the circumstances prevailing in the United States, the institute played an important part This part is not confined to the actual scientific achievements, great as these have been, but extends to the impact of the work of the institute on the thought of those in the United States, and indeed in other countries, who were considering the means by which medicine might be most effectively advanced

The point is of some interest because it is possible in retrospect to be sceptical of the effect that the constitution of the Rockefeller Institute as such had on the scientific output of those who formed its staff in the early years of its existence

There are two reasons for this In the first place, at the time when the Rockefeller Institute was set up the interdependence of many different branches of science in the advance of medicine was not in principle recognised as it is today Secondly, the tendency existing to pursue researches under different headings by parallel and independent lines of approach was reinforced by the constitution of the staff itself As was natural at the beginning of a new venture, the men who were chosen to lead the various divisions of the institute were scientists of distinction and of established reputation in their own fields, within the institute they continued to develop their own lines of research largely in independence of their colleagues Whilst these men undoubtedly benefited by the better facilities that the institute afforded, it is arguable therefore that the same result might have been achieved by improving the conditions of their work as individuals in universities, without bringing them together under one roof

Birth of the National Institute

However this may be, there can be little doubt that the impressive example of the scientific output of the Rockefeller Institute, and of the Lister Institute in this country as the range of its effort broadened, must have carried great weight with the members of the Medical Research Committee (predecessors of the Medical Research Council) when they were engaged, just before the first world war, in formulating their policy At any rate one of their first decisions towards the implementation of this policy was to establish centralised laboratories to be staffed by full-time investigators, it was this decision that gave birth to the National Institute for Medical Research It is noteworthy that no defined limits were set to the scope of the work to be carried out in the centralised laboratories, or indeed to any work to be organised by the Medical Research Committee, other than the broad framework laid down in their general declaration of policy This declaration contained two key sentences, which I have quoted on previous occasions, but which I shall quote again now because of their immediate relevance to the functions of a research institute in the field of medicine

> "The object of the research is the extension of medical knowledge with the view of increasing our power of preserving health and preventing or combating disease But otherwise than that this is to be the guiding aim, the actual field of research is not limited and is to be wide enough to include, so far as may from time to time be found desirable, all researches bearing on health or disease, whether or not such researches have any direct or immediate bearing on any particular disease or group of diseases, provided that they are judged to be useful in promoting the attainment of the above object."

This statement continues to express the policy of the Medical Research Council, so that the evolution of the work of the Council, and particularly of the National Institute for Medical Research which I have to discuss, whether or not it is judged useful in the event, has at least not been inhibited by any undue restrictions

1920-1958

Although the decision to set up the National Institute was taken before the beginning of the first world war, and certain staff appointments were made at that time, the start of actual work was delayed by the war, and it was not until 1920 that the laboratories could be occupied, the institute has thus been in active operation for nearly forty years The initial appointments to the staff were made with the idea of bringing together a group of workers who would be able between them to carry out researches in all branches of non-clinical medical research, the same principle continues to operate at the present time At the outset this meant that the subjects to be represented were physiology and pharmacology, pathology and bacteriology, and chemistry, including biochemistry, in the emphasis that they laid on the latter subjects the Medical Research Council were ahead of their time

From its very modest beginning, when the total number of people employed must have been well under 100, the institute has grown to its present large size, in which there is a professional (i e, medically and scientifically qualified) staff of 142 and a total average population, including visiting workers, of about 550 This growth has been a continuous process, although the rate of expansion has naturally varied from time to time, having reached its maximum immediately after the last war It is important to note that expansion has never been encouraged for its own sake, it has been allowed to take place only when there has been a definite demand for extension of the work in one or other direction This means that the growth of the institute is in itself a reflection of the broadening in the basis of medical research during the last forty years Moreover the history of the institution is now long enough to justify an attempt to assess its contribution to the advance of medicine, and thus, taking it as an example, to form some judgment of the wisdom in general of devoting large resources to this particular type of development

I have no intention of trying to base this assessment on enumeration of the scientific achievements of workers at the institute I shall only speak of a specific line of investigation in so far as it serves to illustrate the advantages and disadvantages of work within a large research institute But let us first consider the more general question of planning of research

Planning of Research

It is important to keep in mind that we are thinking of research which, although it may require the application of the methods of chemistry, physics, and even mathematics, is directed towards a biological objective None would deny that in the exact sciences it is often possible in advance to define a problem with reasonable precision, to formulate the method of approach, and to reach some approximate idea of the type and number of people who are likely to be required for its solution In such a case the exercise of forethought in planning may well be rewarded by more rapid and economical attainment of the object Even here, however, where formal planning undoubtedly has its place, rigidity is at all costs to be avoided the behaviour of the materials to be employed may be predictable, but that of the research-workers is not, and any system is to be deprecated that will make it less likely for the research-worker to be on the alert for the new incidental observation which may ultimately turn out to be much more important than the project in hand

This consideration is even more to the point in biological work, where not only is the behaviour of the workers unpredictable but that of the experimental material as well The complexity of biological material is such, and the variety of the techniques required for its adequate study is so great, that it is impossible at the outset of a major research to foresee the range of work that will have to be covered Under such conditions formal planning can serve little purpose, and any attempt to apply it is likely to be restrictive and therefore deleterious On the other hand the protean nature of many biological problems implies that their solution may more readily be achieved by a suitable grouping of workers which can be increased or restricted according to the demands of the work If certain prerequisites are satisfied, the formation of such useful groupings should be easily brought about within a research institute, and indeed in the ideal case they may be expected to develop spontaneously . The prerequisites are (1) that the institute should be large enough, in the sense that the scientific staff will include men covering a sufficiently wide range of disciplines, (2) that the internal organisation should be flexible, and

(3) that personal relationships are such that members of the staff are willing, for a time at least, to set aside their individual preoccupations in order to collaborate with their colleagues

The sort of process that I have indicated could be illustrated by the development of several major researches in the National Institute for Medical Research I shall choose for my present purpose research on viruses, partly because this has been one of the more important activities of the institute throughout its history

Administrative Division but Working Contact

At the outset, when very little was known of the nature of viruses, their study was naturally regarded as an extension of bacteriology, and the first to undertake the work were men whose training had been in bacteriology and experimental pathology Owing to the peculiar properties of viruses, however, and in particular to their small size, existing technical methods soon proved inadequate, and the group was supplemented by optical research-workers who increased the range of microscopy by developing the use of ultraviolet light, and by a physical chemist who devised methods of estimating the size of viruses by the use of filtration membranes of graded porosity

Up to this stage the total scientific staff of the institute was still so small that it could be regarded as a single group, and there was no very clear demarcation into divisions Under these circumstances the physicists and chemists who joined in the virus researches could pursue their own interests, at the same time participating in the special work of the virus group By the time that the next major technical advance capable of contributing to virus research became available—namely, electron microscopy—the increasing size of the institute had necessitated its organisation into a number of divisions for administrative purposes The fact, however, that the responsibility for electron microscopy as a technique naturally fell to the division of biophysics did not in any way interfere with the fullest application of the method to the work of the division of virus research, on the contrary it encouraged the closest link between the two divisions, and this link has proved to be of much mutual benefit Similarly the period during which research on viruses has reached its present high state of development has also been the period that has seen the most rapid growth of biochemistry, particularly the descriptive and dynamic biochemistry of the cell The application of biochemical thought and technique to virus research has not been neglected and is rapidly growing in importance Here again is the basis for the links that have been formed in the institute between the division of virus research and those of chemistry and biochemistry

Virus research, then, in the particular institute that I am dealing with, involves the activities of many people The nucleus of the work is in the hands of the members of the division of virus research itself, these are men and women whose interest in viruses is primarily biological and medical, in so far as an organised team exists, they constitute the team In a subject of this sort, however, as in many other branches of medical research, the fringes of the effort may often turn out to be the growing points, and these potentially important fringes are studied, as opportunity offers, with the aid of workers in other relevant disciplines whose own primary interests may lie in quite different directions In my opinion the attempt to achieve effective working arrangements of this kind should be the principal aim of those who are responsible for the organisation of research institutes, because I believe that when they are achieved they constitute a service to scientific research not easily provided in any other sort of institution

Advantages of an Institute

On a more practical level a great advantage that a large research institute should be able to offer is the provision of the best technical facilities with considerable economy

The increasing elaboration of technical methods and the consequent increase in the cost of scientific research is only too apparent to all of us, nor is it possible always at the outset of a research programme to forecast accurately the type of equipment that will be required In a generally well-equipped institute, however, the major pieces of special apparatus will be found in one or other of the divisions where their primary use may happen to lie It is perfectly possible to have an understanding that, whilst the equipment is provided in the first place for the use of the laboratory where it is situated, it must be made available within reason to any other worker in the institute who finds himself in urgent need of it for the development of his research

Pooling of resources should ensure that no research-worker is frustrated in his work by lack of adequate technical facilities

Theoretically, of course, there is no reason why medical research, of the type that I have illustrated by reference to work on viruses, should not be developed as well or better elsewhere than in a research institute A university with first-class scientific and medical faculties will possess in all a far greater number of talented investigators than any research institute can hope to gather within its walls Similarly the total amount of technical equipment in the university will be greater The claim of the research institute to be able to render a unique service in medical research must rest therefore on the demonstration that it has some special quality which a collection of university departments cannot provide, however high may be their individual standing

I believe myself that such a quality does exist and that a basic necessity for its acquisition is the assembly under one roof of a collection of people with widely differing scientific interests but working together with a common sense of purpose It was said, I think by Alan Gregg, that a prerequisite for effective collaboration in research is that you should not have to put on your hat when you go to see the man you want to talk to There is certainly much truth in this, but there is an equally important requirement, which is that the man you consult should be ready to listen It is certainly much easier to develop an atmosphere in which effective mutual consultation can take place within a research institute than it can ever be in a university

Indeed, paradoxical as it may seem at first sight, the better the quality of individual university departments, the less easy may mutual consultation between their workers become, for high scientific quality in a university department tends to be associated with intense preoccupation with the subjects of investigation and a corresponding reluctance to divert intellectual effort to the problems of others, moreover it will inspire personal affection for and loyalty to the department itself rather than to the larger institution of which it is a part Furthermore, even given the utmost degree of friendliness and good will, the position of a member of one department entering another as a guest to make use of its valuable equipment can never be easy

Conditions of Success

Within a large research institute the divisions will of course correspond in a sense to the departments of a university faculty, and the head of a division, if he has, as he ought to have, some qualities of leadership, will naturally do his best to see that the standard of work in the laboratories under his care is as high as he can make it. On the other hand the essence of academic work is the pursuit of knowledge for its own sake without regard to practical issues; the essence of work in a research institute is pursuit of knowledge with the greatest degree of intellectual freedom that is consistent with mindfulness of the objects for which the institution was established. The difference, though subtle, is very real and is profound in its effects; for it will mean, if the spirit of the institute is as it should be, that the subjects for research in the different divisions are chosen not only for their own interest but for their potential contribution to the common effort. This in its turn will mean that the loyalties of the workers will be to the institution as a whole rather than to their local habitation within it, and thus may be prevented the growth of barriers that would otherwise form between groups of investigators with differing interests.

It goes without saying that the state of affairs that I have indicated as being desirable, and indeed in my opinion essential, if a research institute is to make its proper contribution does not come about automatically. The mere assembly under one roof of a number of able people, covering between them the required range of disciplines, is but the first small step. I have, indeed, ventured to criticise the Rockefeller Institute in its early days for the very reason that the effort put into its establishment, magnificently successful as it was in collecting men of talent, seems to have stopped at that point. Very positive action is required to carry matters further, and the responsibility for this rests on those who are called upon to direct research institutes.

I have already mentioned three prerequisites for success—namely, sufficient range of scientific competence, a flexible organisation governed by a liberal policy, and good personal relationships. The first and second of these depend on the employing organisation and the director working together, the third on the measure of success that the director may achieve in gaining the confidence of his colleagues. Even though these basic requirements are reasonably fulfilled, the need for constant vigilance remains. The tendency for groups of people with different intellectual interests to segregate from one another is always strong and must at all costs be combated within a research institute: the most effective weapon against this tendency is the development of researches involving many people with different outlooks and different approaches to the problem. Over and above this it is essential to preserve an atmosphere in which any member of the staff feels free to seek the help of any of his colleagues, and in which everything possible is done—by means of colloquia, open days, and any other available means—to spread knowledge of and interest in the work of individual laboratories through the institute as a whole. When all has been done by authority that can be done the happiness of any individual member of the staff and his usefulness depend on himself. In a large and active institute with a free atmosphere the opportunities for intellectual stimulation lie to his hand and it is for him to use them if he will. He can gain so much by varying his companions at the luncheon table and in the coffee room; he can lose so much by making no contacts outside his immediate associates.

Objections to Institutes

Having discussed some of the advantages that can, under the right conditions, be provided by research institutes, giving them a useful place in medical research, I must now consider some of the criticisms that are levelled at institutions of this kind—criticisms that are neither infrequent nor lacking in vigour.

I have already mentioned some of the dangers and difficulties inherent in research institutes, of which I have become conscious from my personal experience; but the criticisms that are commonly made from outside are of a somewhat different character. These criticisms are to some extent mutually contradictory; thus the academically minded critic finds it hard to believe that the higher flights of scientific investigation can be attained within an organisation that is subject to any sort of restriction or limitation of objective, whilst the practically minded critic sees the research institute as a hothouse for the development of the ivory-tower mentality. Again, it is said on the one hand that the staff of a research institute tends to be static and therefore inevitably to accumulate dead wood, on the other that by offering a sheltered existence with no distractions from research the institute drains the limited pool of talent of people who would be better employed in universities. These contradictions do not, however, necessarily deprive the criticisms of substance, and they must be examined.

The answer to the extreme academic objection that original investigation can flourish only in conditions of complete academic freedom is a simple one; it is contained in the record of major scientific discoveries that have come from medical research institutes in this and other countries. This statement is not merely a matter of personal opinion; it is substantiated by the opinion of the scientific community as shown by the recognition of workers in medical research institutes, internationally by the award of Nobel prizes, in this country by election to the Royal Society, and in other countries by analogous distinctions. In the light of this record it is manifestly untrue to maintain that the atmosphere of a research institute is necessarily less encouraging to original thought than that of a university.

The contrary argument that work in a research institute leads to loss of contact with reality has more cogency. If we accept the view that the maximum of intellectual freedom is an essential feature of a satisfactory institute, such an institute will attract the type of person capable of original thought, and we cannot be surprised that some workers placed in an atmosphere of this kind will become engrossed in the pursuit of their own ideas and will become totally uninterested in any practical application of their work. This must be accepted as a risk inherent in the research-institute system; the lack of practical interest on the part of the worker himself can be countered by increased watchfulness on the part of the head of his division and the director. Nor must we forget that even if there should be no perceivable practical outcome of the work, *this may nevertheless constitute a scientific advance intrinsically worth having*.

The questions of the effect of life in a research institute on the staff, and of the competitive requirements for scientific staff of research institutes and university departments, are best taken together. It is not to be denied that a danger of stagnation exists for the scientific staff of a research institute, but much can be done to combat this danger. It is also true that university departments and research institutes must draw on the same pool of talent, but here again it is possible to adopt a mutually helpful policy rather than to indulge in cut-throat competition

The danger of stagnation can be partly dealt with at the earliest stage by the conditions of employment It will be generally admitted that a career of scientific research is the least predictable of all careers for the young man setting out on it, it is an adventure, and for his employers a speculation It is therefore surely fair and reasonable that junior workers in research institutes should be employed on short-term appointments of three to five years until it is apparent that they have chosen the work for which they are fitted If this proves not to be so there is then still time for them to start another career

Stagnation of a more serious character can occur at a later stage It is a mistake to regard work in a research institute as a sheltered and unexacting occupation Economically sheltered it may be, but it can be far more exacting psychologically than many apparently more arduous forms of work This is often not apparent to an individual worker for a number of years, while his mind is most active he will welcome the unparalleled opportunity that a research institute can offer for the pursuit of his own research without any other responsibility For many men, however, and indeed in my experience for most, there comes a time when the satisfaction to be obtained from their own efforts ceases to be enough This time is critical, if a real sense of inadequacy and frustration is allowed to develop a good man may be lost, ceasing to be a useful member of the research institute, and at the same time having no heart for any other job

Here again there are ways in which this danger that besets research institutes can be met It does not follow that because a research-worker in early middle age has lost his desire to pursue research at the expense of all other activities he has therefore lost his usefulness On the contrary he may well have acquired other qualities of experience and judgment, and the capacity for imparting knowledge, that increase his potential value to society if the right work can be found for him Sometimes the problem can be solved within the research institute itself, if there exist official duties in which he can be given a share, more often, however, it is better for him to move elsewhere, and it is in this connection that ease of transfer from the staffs of research institutes to those of universities becomes so important

If such a transfer is to take place it is obviously only by good fortune that it can occur at the optimum moment both for the research institute and the university Since it is on the universities that the supply of future research-workers must depend, it seems to me self-evident that when there is an apparent conflict of interest the claim of the university must come first No research director in his senses would wish to compete with a university for the services of a man who would obviously make a good professor, even though *he may still be a most valuable* member of his scientific staff, *on the contrary, if he is wise*, he will encourage such a man to seize his new opportunity whilst he has full vigour to make use of it What I have just said is based not on armchair theory but on practical experience There are about twenty university professors of medical subjects, now or previously in office, in universities in this country and the Dominions, as well as several readers, who have earlier served as members of the staff of the National Institute for Medical Research In no case was any attempt made to dissuade the man from taking the university post, in no case did a man leave the institute worn out by his research and seeking only to subside into his professorial chair On the contrary, all these men have continued to be active investigators and by the quality of their departments they have made their full contribution to university life This is part of the record of the National Institute for Medical Research in which I personally feel great pride

The research institute, I believe, not only has a part to play in medicine as an efficient instrument for the advance of knowledge, but so far from being in destructive competition with universities, can complement their efforts, and may even have the good fortune to serve as a nursery for first-class heads of university departments The claim that the research institute can make a unique contribution rests on the assumption that its total effort will be more productive than would be the sum of the efforts of its constituent parts were these not welded into a closely knit scientific community I have tried to show how this claim can be substantiated, and at the same time I have been at some pains to point out the dangers to which research institutes are exposed and the conditions that are necessary for success The pitfalls are many and the frequency with which we fall into them is high, nevertheless the rewards of success when it does come are so great that the effort to maintain and develop institutes for medical research can surely be regarded as worthy of human endeavour

Two Unsolved Problems

Before I end there are two major unsolved problems which I must mention All that I have said refers to institutes concerned with laboratory research only We are, however, considering the place of the research institute within the framework of medicine as a whole If we agree that the laboratory research institute has its function and can under the right conditions be of great value, the question arises as to whether this value would be much enhanced by a close association with clinical work This brings in its train the second question, which is whether a strengthening of clinical research, similar to that achieved on the laboratory side, could be effected by the establishment of clinical research institutes

These two questions are far too large to be discussed at this juncture On the first I would only say that no-one who works in a laboratory institute for medical research can fail to be conscious of a defect in the present system It is indeed possible to ensure that discoveries made in the laboratory that have practical application are promptly brought into the right hands so that they may be properly applied, on the other hand it happens not infrequently that a research started as a laboratory investigation develops in such a way that observations on patients become desirable both from a scientific point of view and in order to study the application of the work to treatment of disease With all possible good will on both sides, the establishment of a fruitful laboratory-clinical collaboration at a distance offers formidable difficulties, and in the event frustration and loss of effort can undoubtedly result For this and other reasons it is tempting to suppose that a closer association of laboratory research units and clinical work would be advantageous, certainly to the laboratory workers and perhaps to the clinical investigators

It is tempting further to assume that the advantages would be enhanced if the association were with an institute for clinical research covering many different branches of medicine The success that has already been achieved by the United States National Institutes of

Health points indeed in this direction It does not follow, however, that an organisation appropriate to the special circumstances prevailing in the United States will necessarily succeed in other countries, and it seems to me that the question of the feasibility and usefulness of institutes for clinical research in general remains open Nevertheless I would like to end my lecture leaving this question in your minds It is at least worth thinking about. For if the answer is yes, we might, by forming institutes for clinical research and associating or combining them with laboratory research institutes, forge weapons for the advance of medical science more powerful than any that we now possess

EXPERIMENTAL PRODUCTION OF ENDOMYOCARDIAL FIBROSIS

HANS SELYE
M.D , Ph.D Prague, D Sc. McGill
PROFESSOR AND DIRECTOR, INSTITUT DE MEDECINE ET DE CHIRURGIE EXPERIMENTALES, UNIVERSITÉ DE MONTREAL, MONTREAL, CANADA

THE term "endomyocardial fibrosis" describes structural derangements of uncertain ætiology As Brigden (1957) points out, minor degrees of such derangements are common in many of the chronic forms of myocardial disease, but they are generally thought to be essentially different from the great endocardial thickening which appears to be the result of a specific disease particularly rife in Africa. Typical cases of endomyocardial fibrosis are common in Uganda (Ball et al 1955, Davies and Ball 1955), the Sudan (O'Brien 1954), and Eastern Nigeria, where allegedly 40% of the patients with heart-disease admitted to hospital have endomyocardial fibrosis (Nwokolo 1956). However, the disease is likewise not unusual in the Middle East (Bedford and Konstam 1946), and it has occasionally been observed in the United Kingdom (Hughes and Smith 1953, Evans 1949) the United States (Thomas et al 1954, Elster et al. 1955, Hoffman et al 1955), Switzerland (Loeffler 1936), and other countries The subject has been reviewed at some length by Gray (1951 and by *The Lancet* (1952)

Stemmermann (1957) described a malady under the name of "idiopathic endomyocardial necrosis" which he believed to be related to the typical endomyocardial fibrosis In his patient the cardiac lesions were associated with extensive morbid changes in the pancreas Stemmermann also obtained material, from twelve additional cases, through the Armed Forces Institute of Pathology (Washington, D C.), and noted that in seven of these there were pancreatic lesions—especially, focal necrosis of acinar tissue and necrosis of fat. Sometimes the pancreatic ducts were plugged with secretion and pancreatitis developed Stemmermann concluded that "the basic pattern of the pancreatic changes fits into the framework of the general adaptation syndrome".

Since the causal agent has never been identified, it is not certain that endomyocardial fibrosis is always a manifestation of the same disease, nor can it be proved that subendocardial necrosis represents an early stage of endomyocardial fibrosis Most investigators believe that endomyocardial fibrosis is due to some infection or nutritional deficiency, but this has not been proved, and Stemmermann (1957) expressed the opinion that, under certain conditions, any stressor agent could produce such myocardial lesions

Our interest in this lesion was aroused by the observation that, in various species of laboratory animals, predominantly subendocardial necroses can be produced at will by conjoint treatment with steroids and sodium salts This so-called electrolyte-steroid-cardiopathy characterized by necroses (E.S C.N) is sometimes accompanied by focal pancreatic necroses and pancreatitis (de Salcedo and Selye 1957)

The experimental production and prevention of the E.S C.N have recently been surveyed in a brief review (Selye 1958a) and in an extensive monograph (Selye 1958b) Suffice it therefore to point out here that, after suitable conditioning with corticoids—particularly with the highly potent 2α-methyl-9α-chlorocortisol (Me-Cl-COL)—not only electrolytes but even mere exposure to stress (hot or cold baths, surgical trauma, injections of adrenaline, noradrenaline, vasopressin, and many other drugs) can produce predominantly subendocardial necroses in the heart, and that these can be prevented by the oral administration of KCl or $MgCl_2$

In view of the great prevalence of endomyocardial fibrosis in certain parts of the world, it seemed of interest to establish whether this disease is related to the E.S C.N , because, if it is, the successful prevention of the latter by KCl and $MgCl_2$ may be a guide to the nutritional prophylaxis of clinical endomyocardial fibrosis

Experiments

Materials and Techniques

Forty female Sprague-Dawley rats with a mean initial body-weight of 98 g (range 90–107 g) were subdivided into four

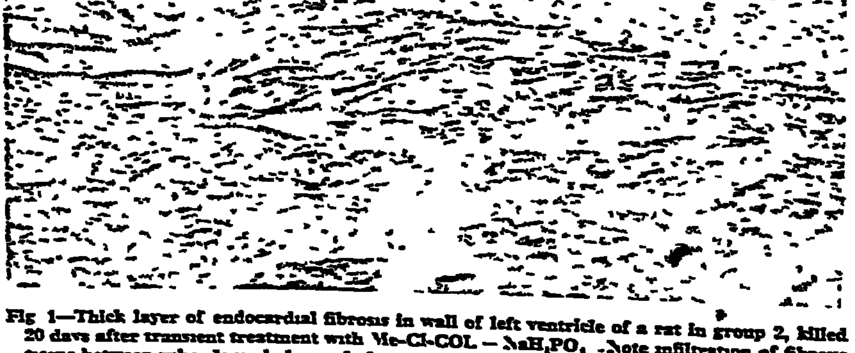

Fig 1—Thick layer of endocardial fibrosis in wall of left ventricle of a rat in group 2, killed 20 days after transient treatment with Me-Cl-COL – NaH_2PO_4 -Note infiltration of fibrous tissue between subendocardial muscle-layers. (Fuchsin. ×75)

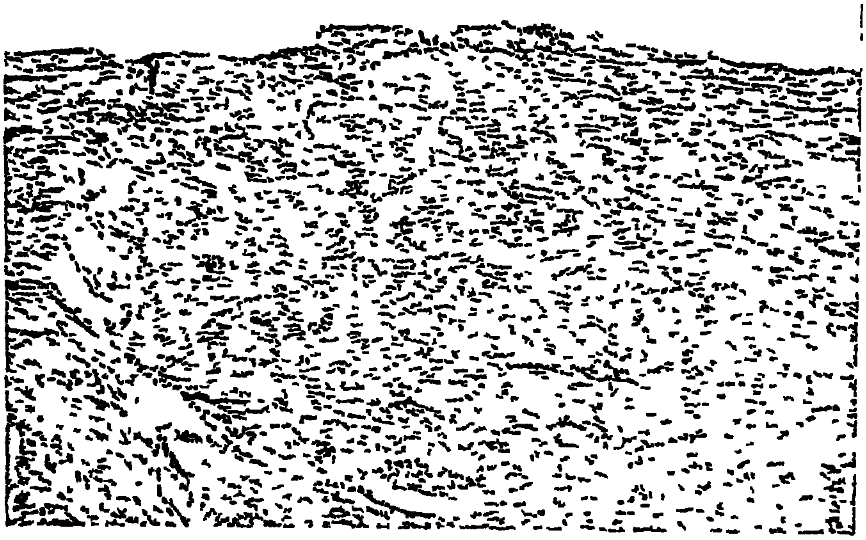

Fig 2—Comparable region of the endocardium of a rat in group 4, showing preservation of normal structure, owing to prophylactic treatment with $MgCl_2$. (Fuchsin ×75)

equal groups. All the rats were fed exclusively on 'Purina Fox Chow' (Ralston Purina Co.) throughout the period of observation. In addition, during the first 30 days they all received 1% $NaH_2PO_4 \cdot H_2O$ as their only drink, and Me-Cl-COL in the form of microcrystals of its acetate, at dose of 50 µg in 0·2 ml of water, subcutaneously, once daily. Groups 1 and 2 were not otherwise treated, whereas groups 3 and 4 received, in addition to the Me-Cl-COL+NaH_2PO_4 treatment, 1 mM of $MgCl_2 \cdot 6H_2O$ in 2 ml of water, twice daily, by stomach tube, during the first 30 days. By the 30th day two animals in group 1 and three in group 2 died with obvious manifestations of E.S.C.N. (extensive and predominantly subendocardial necroses with secondary inflammation). None of the rats in groups 3 and 4 died.

On the 30th day all the treatments were discontinued, and the survivors in groups 1 and 3 were killed. Their hearts were fixed in neutral formalin and stained with our fuchsin technique (Selye 1958b), which shows up early prenecrotic degenerative changes in myocardial muscle-fibres. The intensity of the cardiac lesions was assessed in terms of an arbitrary scale of 0–3, and it was found that on the 30th day the mean intensity of the myocardial necroses was 1·5±0·25 in the rats in group 1, whereas the animals of group 3 (which received the additional $MgCl_2$ treatment) showed no histological evidence of myocardial damage.

20 days later—i.e., 50 days after initiation of the treatment—the rats in groups 2 and 4 were killed, and their hearts were histologically examined by the same technique. The findings in these latter groups represent the principal subject of our study and will be discussed in detail below.

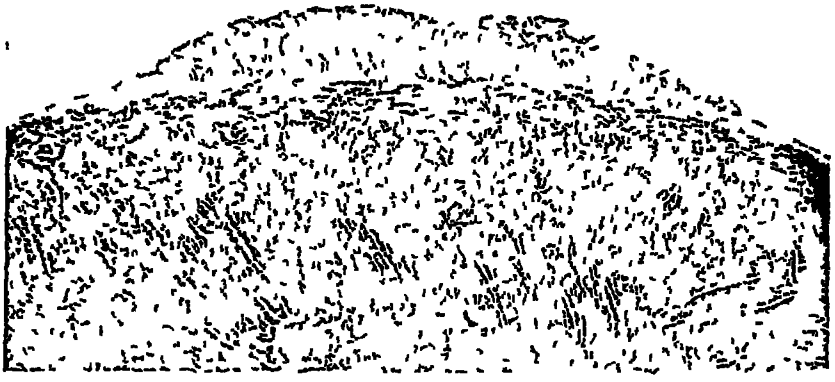

Fig 4—Circumscribed patch of fibrous pericarditis on the surface of the left ventricle of rat in group 2. Such pericardial lesions are much less common in rats so treated than is endomyocardial fibrosis. (Fuchsin ×25)

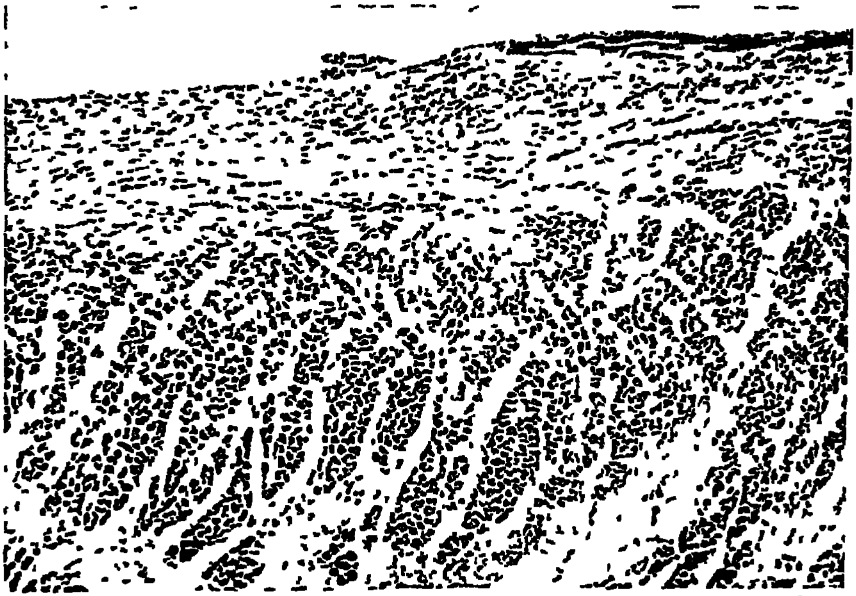

Fig 3—Particularly severe endomyocardial fibrosis in the wall of the right ventricle of a rat in group 2. (Fuchsin ×75)

Results

Two of the rats in group 2 exhibited no detectable histological change in the myocardium on the 50th day—i.e., at the end of the 20-day rest period. Apparently here, whatever minor lesions might have been present on the 30th day, when treatment was discontinued, had healed without leaving any permanent scar. However, in all of the remaining eight animals, thick layers of subendocardial fibrosis had developed in those locations where the necroses had been most plentiful in the rats of the corresponding group 1 which were killed immediately after discontinuation of treatment. In some of these rats the endocardial fibrosis was accompanied by patches of pericardial and myocardial fibrosis.

The histological appearance of these changes is illustrated in figs 1-4 The resemblance between this experimental lesion and the morbid changes found in patients who die of endomyocardial fibrosis is quite striking In the myocardium of the rats in group 4 no pathological change was detected

Discussion

It is clear from these experiments that, although small foci of myocardial necroses can disappear after discontinuation of the electrolyte-steroid treatment without leaving a trace, the larger foci of the E S C N heal by the substitution of dense connective tissue for the dead muscle-fibres Since the necroses of the E S C N tend to be localised predominantly in the subendocardial layers, the fibrosis is also most conspicuous in these regions It is evident, furthermore, that $MgCl_2$ not only prevents the development of the initial myocardial necroses but also forestalls the secondary fibrosis

We repeated this experiment on rats which received the same treatment with Me-Cl-COL plus NaH_2PO_4 for 30 days The rats that did not die spontaneously were killed after 30 days, no rest period was allowed in this experiment The results were essentially the same except that fresh subendocardial necroses and endocardial fibroses often occurred simultaneously in the same heart $MgCl_2$ again prevented the development of all myocardial changes

It remains to be seen whether electrolytes and steroids also have a decisive rôle in the development of clinical endomyocardial fibrosis, and whether $MgCl_2$ and other electrolytes that are known to prevent the E S C N (e g, KCl) could here be used to advantage as prophylactic agents Further studies will also be necessary to verify whether a high dietary intake of fats, carbohydrates, and certain Na salts which sensitise laboratory animals for the production of an E S C N (Selye 1958b), plays a part in the pathogenesis of the structurally similar spontaneous disease of man

Summary

Experiments on rats indicate that a comparatively brief period of treatment with certain corticoids, such as 2α-methyl-9α-chlorocortisol (Me-Cl-COL), plus Na salts (e g, NaH_2PO_4), produces myocardial necroses which are predominantly localised in the subendocardial layers If, in addition to this treatment, $MgCl_2$ is administered, the development of these changes is prevented

After discontinuation of treatment, the cardiac necroses thus elicited tend to heal by the formation of thick scar tissue, producing a condition resembling endomyocardial fibrosis

In rats in which these cardiac necroses were prevented by the prophylactic administration of $MgCl_2$ the secondary fibrosis did not develop

The possible clinical implications of these findings are briefly discussed

These investigations were supported in part by Research Grant no H-3688 from the National Heart Institute, U S Public Health Service, and by a grant from the Upjohn Company, who also supplied 2α-methyl-9α-chlorocortisol

CONTROL OF GASTRIC AND PANCREATIC SECRETION BY INHIBITION OF CARBONIC ANHYDRASE*

HENRY D JANOWITZ
M D Columbia
ASSOCIATE ATTENDING PHYSICIAN FOR GASTROENTEROLOGY, AND CHIEF, GASTROINTESTINAL CLINIC, THE MOUNT SINAI HOSPITAL, NEW YORK

THE most striking relation between the stomach and the pancreas is the way in which the gastric mucosa secreting an acid solution with a H^+-ion concentration of more than 160 mEq per litre elicits from the pancreas an alkaline fluid with a corresponding bicarbonate-ion concentration of 150 mEq per litre or more

This symmetrical integrated process has an inherent, almost æsthetic, interest, but, beyond this, clinicians have been preoccupied for the last fifty years with either controlling or suppressing this mechanism for their therapeutic ends Almost the whole of modern treatment of peptic ulcer is an attempt to abolish the stomach's secretion of hydrochloric acid, on the supposition that the ulcer is a localised area of autodigestion of gastrointestinal mucosa by hydrochloric acid

Almost the whole of therapy in acute inflammation of the pancreas is a similar effort to suppress pancreatic secretion, based on an analogous supposition that this lesion is due to localised autodigestion by pancreatic secretion

These therapeutic concepts may be wrong, but it still seems desirable to be able to control and thus to suppress the secretions of these digestive glands

If we leave aside total extirpation of the gastric glands (perhaps the ultimate aim of surgical therapy), the current useful therapeutic agents either neutralise already elaborated acid or else interfere (with variable success) with the nerves which stimulate the gastric glands A more logical approach would be direct control of the intracellular processes of secretion—inhibition at the source This is not a priori impossible, since there exist precedents for such intracellular therapeusis—e g mercurial inhibition of the renal tubular reabsorption of fluid and solutes in clinical œdema, and probenicid inhibition of the reabsorption of urates in gout

The studies of gastric and pancreatic carbonic anhydrase which are here reviewed had as their genesis the hope of establishing a safe, efficient, and practical method of controlling these digestive secretions at the cellular level This hope was not achieved, but the results of these studies indicate that such a chemotherapeutic aim is feasible and give further insight into the complex intracellular processes of digestive secretion

Inhibition of Gastric Secretion by Inhibition of Gastric Carbonic Anhydrase

Historical

The considerable literature on gastric carbonic anhydrase was reviewed by Davenport (1946a) Here it is only necessary to recall the following points

Davenport (1939) showed that this zinc-containing enzyme was present in highest concentrations in that part of the gastric mucosa which contained the highest proportion of oxyntic cells This discovery suggested that carbon dioxide arising in these cells during metabolic processes is hydrated to carbonic acid under the catalytic influence of the enzyme, and that subsequent ionisation of carbonic acid provides hydrogen ions for gastric secretion

Inhibition of acid secretion in the dog under the influence of thiocyanate appeared to support this suggestion strongly, but Feldberg et al (1940) showed that sulphanilamide, a more potent carbonic-anhydrase inhibitor than thiocyanate, did not inhibit acid secretion, and Davenport (1946b) withdrew his theory Yet studies (Davies and Edelman 1951) on the secretion of the isolated amphibian stomach indicated that an external source of bicarbonate was needed, and that carbonic-anhydrase activity was needed to maintain high rates of secretory activity

This discrepancy between the in-vitro studies and the failure of inhibitors of carbonic anhydrase of the sulphanilamide class to inhibit gastric secretion of acid in vivo was disturbing Further, Davies and Roughton (1948), on the basis of the relative concentrations of enzyme in red blood-cells—and in gastric mucosa, had concluded that no inhibition in the living animal was to be expected, because the transport of carbon dioxide by the blood would be so seriously affected as to lead to the speedy death of the animal

Studies with Acetazolamide

Such was this unresolved situation when our interest was stimulated by the synthesis of a series of carbonic anhydrase inhibitors by Roblin and Clapp (1950) searching for more effective diuretic agents Several heterocyclic sulphonamides were created as carbonic-anhydrase inhibitors Acetazolamide received most study, but the antisecretory activity of related substances was also explored

Studies in Animals

Acid secretion was investigated in dogs fitted with vagally denervated (Haidenhain) pouches of the body of the stomach, secreting under the continuous influence of subcutaneous histamine When intravenous acetazolamide 20–60 mg per kg of body-weight was given to these animals, there followed, after 20–80 minutes, a profound fall in the rate of secretion of hydrochloric acid, ranging between 70% and 97% (average about 90%) (Janowitz et al 1952a) This persisted for from three to six hours and appeared completely reversible Most striking was the observation that this degree of inhibition of gastric carbonic anhydrase was well tolerated by the dogs Studies based on the topical application of acetazolamide to the gastric mucosa indicated that the results were due to local action on gastric carbonic anhydrase and not necessarily related to the amount of acetazolamide circulating in the plasma (Janowitz et al 1952b) This inhibition was also quite independent of alterations in the plasma-electrolyte level

Studies in Man

With some trepidation the influence of acetazolamide was investigated in man in a similar way (Janowitz et al 1957) Healthy volunteers and patients with peptic ulcers of the stomach, duodenum, or jejunum were studied during phases of unstimulated interdigestive (basal) secretion and after histamine stimulation Profound inhibition, up to complete suppression, of the secretion of hydrochloric acid was produced by the intravenous infusion of large doses (73–154 mg per kg of body-weight) of acetazolamide given in 1 to 8 hours Oral acetazolamide was ineffective, probably because such large doses were not given Although there was tingling of the extremities, anxiety, and breathlessness with doses greater than 114 mg per kg of body-weight, acetazolamide was surprisingly well tolerated

These results in animals and man indicated quite convincingly that carbonic anhydrase is intimately involved in the mechanisms of the secretion of hydrochloric acid by the mammalian stomach, and that a suitable carbonic-anhydrase inhibitor can effectively suppress this secretion in the intact organism without untoward results The extremely large doses required and, especially, the route of administration are cumbersome and restrict the therapeutic usefulness of acetazolamide In terms of our goal this method is safe and efficient but unpractical

Role of Carbonic Anhydrase in Secretion of Acid

The bulk of evidence at present indicates that the inhibition of carbonic anhydrase affects only the secretion of H^+ ions in the stomach, in contrast to its profound effects on the secretion of Na^+ and K^+ ions in the kidney Experiments, presented in preliminary form by Colcher et al (1952), lead to the conclusion that acetazolamide does not affect any H^+-K^+ or H^+-Na^+ exchange mechanisms in the stomach The role of carbonic anhydrase in gastric secretion is therefore believed to be solely concerned with the acid-secreting mechanism

Evidence based on the "alkaline tide" of the urine and on gastric arteriovenous CO_2 differences, and, especially, the studies of Davies (1951) on the metabolism of the isolated gastric mucosa indicate that, for each mole of HCl secreted into the lumen of the stomach, an equal amount of bicarbonate plus lactate appears in the nutrient (interstitial) fluid This bicarbonate is derived from plasma CO_2 and from CO_2 arising in the cell as the result of metabolic processes In both cases the CO_2 is hydrated to form carbonic acid under the catalytic influence of carbonic anhydrase, and this acid ionises to form H^+ and HCO_3^- ions

$$H_2O+CO_2 \rightleftharpoons H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$

During the secretion of H^+ ions at the mucosa an equimolar amount of OH^- ions is formed at the inner surface of the canaliculus of the parietal cell Accumulation of these OH^- ions, with consequent disruption of the milieu interieur of the cell, is prevented by neutralisation with HCO_3^- The present experiments indicate that the uncatalysed rate of the reaction written above is not rapid enough in the absence of carbonic anhydrase to meet the full demands of an actively secreting mucosa Consequently the rate of acid formation falls drastically when inhibitors are administered

Inhibition of Pancreatic Secretion by Inhibition of Pancreatic Carbonic Anhydrase

Historical

The sequence of events in the analysis of the role of pancreatic carbonic anhydrase has followed rather closely the gastric pattern The discovery of the enzyme in the pancreas of various animal species by Van Goor (1940) led him to postulate that the large amount of bicarbonate in pancreatic juice was ultimately derived from the hydration of CO_2 under the enzyme's influence Here again the failure of inhibitors of carbonic anhydrase of the sulphanilamide group to influence secretion significantly cast considerable doubt on its role (Tucker and Ball 1941) Shortly after our discovery that acetazolamide was effective against gastric secretion of acid Birnbaum and Hollander (1953) reported that a similar effect could be elicited in the dog's pancreas

Inhibition of Pancreatic Secretion by Acetazolamide in Man (Dreiling et al 1955)

In these studies duodenal fluid was aspirated, by continuous suction, free from gastric contamination. Pancreatic flow was stimulated by intravenous secretin 1 clinical unit per kg of body-weight because this hormone causes the pancreas to elaborate an isotonic solution of bicarbonate Acetazolamide (given as the sodium salt of 'Diamox') was infused intravenously for 1 hour between successive secretin stimulations Eighteen persons were so studied four had chronic pancreatitis, and fourteen had no disease of the pancreas With doses of 80 mg per kg of body-weight or more there was a profound inhibition of the flow of pancreatic juice and of the output of bicarbonate from the gland The effect on the output of enzyme (amylase) was much less

These results clearly showed that a suitable inhibitor of carbonic anhydrase could significantly suppress pancreatic secretion The method is safe and efficient but cumbersome Acetazolamide has been used by several workers in the treatment of external pancreatic fistulæ with apparent success (Watman 1956, Papastrat and Miller 1958)

Role of Carbonic Anhydrase in Pancreatic Secretion

Dreiling and Janowitz (1956) have shown that acetazolamide has no effect on the secretion of Na^+ or of K^+ by the human pancreas but only on the secretion of HCO_3^- ions stimulated by secretin Secretin has no carbonic-anhydrase activity and does not potentiate the action of carbonic anhydrase in man

In our present formulation the HCO_3^- ions of pancreatic fluid are derived from the hydration of CO_2 (of cellular metabolic origin in part and from plasma CO_2 in lesser part), under the influence of the enzyme Inhibition of the enzyme limits the amount of HCO_3^- ions available for secretion

In addition recent analysis indicates another function for the carbonic anhydrase (Janowitz and Dreiling 1957) It is well known that the HCO_3^- concentration of pancreatic juice is a function of the rate of secretion, varying directly, whereas the concentration of Cl^- ions varies inversely, the sum of $Cl^- + HCO_3^-$ is remarkably close to 160 mEq per litre and isotonic Under the influence of acetazolamide, although the flow and output of HCO_3^- decrease, the level of HCO_3^- tends to remain raised This has suggested a second function for the enzyme participation in a Cl^--HCO_3^- exchange in the ducts of the pancreas, which exchange may be interfered with by the carbonic-anhydrase inhibitors

Future Lines of Approach to Intracellular Inhibition

Much energy has been expended in the effort to find an "ideal antisecretory drug" with cholinergic-blocking action Experimental and clinical studies have defined the limitations of the available compounds which suppress secretion by interfering with the neural pathways for stimulation It seems clear to me that future refinements along this line are not likely to bring the "ideal" any closer in view of the widespread distribution of cholinergic-mediated neural pathways throughout the body, the quest for drugs without significant side-effects seems particularly likely to be fruitless

The present studies indicate that intracellular inhibition of secretion by digestive glands is feasible in the intact human without limiting untoward effects The carbonic-anhydrase inhibitors at present available, however, require large intravenous doses It is not unreasonable to believe that other compounds may be synthesised which are effective in smaller doses Some unpublished evidence suggests that acetazolamide and several of its derivatives may be concentrated within the parietal cells However, the distribution of carbonic anhydrase in several key organs in the body may be the limiting factor to the present experimental approach What is needed is more knowledge of the more specific intracellular enzyme-catalysed processes involved in exocrine secretion Though a considerable amount of information about overall metabolic processes within the gastric mucosa has accumulated, large gaps in our knowledge still exist The recent demonstration by Douthwaite and Booth (1956) of the inhibition of gastric secretion in man by topical application of organic mercury to the mucosa represents a relatively non-specific approach towards the same end

Summary and Conclusion

Administration to man of large doses of intravenous acetazolamide has shown two facts

(1) Carbonic anhydrase plays a vital role in man in the gastric secretion of hydrochloric acid and in the pancreatic secretion of bicarbonate

(2) Inhibition of this enzyme suppresses gastric and pancreatic secretion without untoward disturbing effects

The route of administration and dosage required for currently available carbonic-anhydrase inhibitors makes this approach unpractical at present

Inhibition of the intracellular processes of digestive secretion offers a new and feasible approach to future therapeutic research

BILIARY VESICULAR STASIS

J Dudfield Rose
M B Durh , F R C S
SENIOR SURGEON, NEWCASTLE GENERAL HOSPITAL, ASSOCIATE SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE UPON TYNE

The commonest disorder of the biliary tract is a disorder of its motility—biliary dyskinesia Of a recent series of 200 consecutive cases investigated and treated for biliary-tract disorder, a dyskinesia was found, either alone or in association with some morphological change, in 126 The simplest and commonest form of dyskinesia is a vesicular stasis, a condition in which the gallbladder empties insufficiently This condition was present in 34 of the 126 cases of dyskinesia in this series

Biliary vesicular stasis may be divided into two main groups, hypotonic and hypertonic

Classification of Vesicular Stasis

I *Hypotonic vesicular stasis*
  1 Primary hypotonia
    (*a*) Purely functional
    (*b*) Organo-functional (i e , associated with some morphological abnormality)
  2 Secondary hypotonia
II *Hypertonic vesicular stasis*
  1 Functional or spasmodic
  2 Organic
    (*a*) Stone
    (*b*) Cystic dyskinesia
      (i) Cystic valve
      (ii) Infundibulo-colo-cysticitis
      (iii) Fibrosis of sphincter of Oddi

In the present series there were 20 cases of hypotonic vesicular stasis Chiray et al (1925) in Paris described an atonic distension of the gallbladder which was completely independent of any mechanical obstruction and constituted a definite clinical, radiological, and therapeutic entity

Hypotonic Vesicular Stasis

Hypotonic vesicular stasis is a slowly progressive disease, occasionally with exacerbations It is commoner in women and usually begins early in life The patient complains of dyspepsia, described as a heavy dull feeling in the epigastrium and below the right costal margin which comes on a quarter to half an hour after meals and remains for two to three hours These attacks last three or four days or more and appear to be initiated by the ingestion of fats, eggs, and sometimes fruit and green vegetables Discomfort and pain are felt in the epigastrium and below the right costal margin, and radiate to the dorsolumbar region and to the right scapula and interscapular regions These symptoms have usually persisted for many years before the patient comes to consultation, by which time the attacks have become more frequent and the pain more severe Appetite and weight are lost The attacks of pain, lasting half an hour or so, gradually increase in severity until the crises of pain resemble true colic Uncommonly these severe attacks may be associated with jaundice (in my series of 20 cases of hypotonic stasis, 4 had a history of jaundice, and in only 1 of these was any possible morphological cause found—a stone) and there may be a raised temperature and copious bilious vomiting Associated with these attacks of pain there is often severe headache of a migrainous type

On examination there may be tenderness on palpation below the right costal margin There will be changes in the character, amount, and flow of the gallbladder bile (which is more concentrated and flows for a longer period) obtained either by the Meltzer-Lyon test or by the chronovolumetric estimation of bile (Varela-Lopez 1950)

On cholecystography, the gallbladder is often long and flask-shaped and lies parallel to the spinal column In the erect position the density of the shadow is greatest in the fundus The form of the shadow may be distorted by the surrounding viscera It is, however, impossible to make an accurate diagnosis by means of the " classical " cholecystogram An accurate diagnosis can be made by serial cholecystography (Rose 1958), in which a series of cholecystograms (anteroposterior and lateral) are taken before and at ten-minute intervals after a fatty meal From these the volume of the gallbladder is computed and an evacuation curve is drawn The angle which the long axis of the gallbladder makes with the spine in the lateral view (angle of erection) is measured, the size of this angle is an indication of the tone and the degree of contraction of the gallbladder On serial cholecystography the cystic duct is often visible before the fatty meal is given, the gallbladder evacuates insufficiently at all stages, and there is little or no evidence of active contraction or tone of the gallbladder

It may be impossible to distinguish between a primary and a secondary stasis before operation and manometric investigation (apart from trans-parieto-hepatic vesicular puncture) The peroperative investigations are (1) measurement of the pressure within the biliary tract on a recording manometer, and (2) radiography of the biliary tract after the injection of diodone At operation the gallbladder is in many cases found to be flaccid and slightly larger than normal When pressure recordings are made, the residual pressure in the gallbladder is less than the normal 18 cm of water Peroperative radiography shows that the gallbladder is distended, elongated, and flask-shaped It evacuates easily into the common duct, which is itself hypotonic, and the opaque material flows without resistance into the duodenum and also up into the hepatic ducts The sphincter of Oddi is widely open The common duct is usually widely dilated and evacuates rapidly, the hepatic duct may also be dilated The hepatic and common ducts often form part of a large curve, or they may be sinuous

The treatment of hypotonic vesicular stasis is in the first instance medical, but eventually in most cases there must be recourse to surgery In considering the surgical treatment of hypotonic vesicular stasis it is important to emphasise that an exact diagnosis is a prerequisite and this can be obtained only by manometry and radiography at operation (Mallet-Guy and Rose 1956) It is only by these means that a primary hypotonia may be differentiated from a secondary atony of the gallbladder The surgical treatment of primary vesicular hypotonia is based on the fact that the right greater splanchnic nerve is the inhibitor nerve of the biliary tract (Mallet-Guy and Maillet 1941, Mallet-Guy and Guillet 1942) In my series of 20 cases of hypotonic vesicular stasis I performed a right splanchnicectomy in each case Each patient has been followed up by interview at intervals of one, two, three, six, and twelve months after operation and then annually In classification of the results from operative interference in my series of disorders of the biliary tract and pancreas, the following groups have been used throughout

Group Ia No symptoms and no dietary restrictions
Group Ib No symptoms but some dietary restrictions
Group II Persistence of some minor symptoms—i e , symptoms less severe than before operation (the presence of even one symptom puts the patient into this group)
Group III Persistence of some major symptoms—i e , symptoms as severe or even more severe than before operation (the presence of even one severe symptom puts the patient into this group)

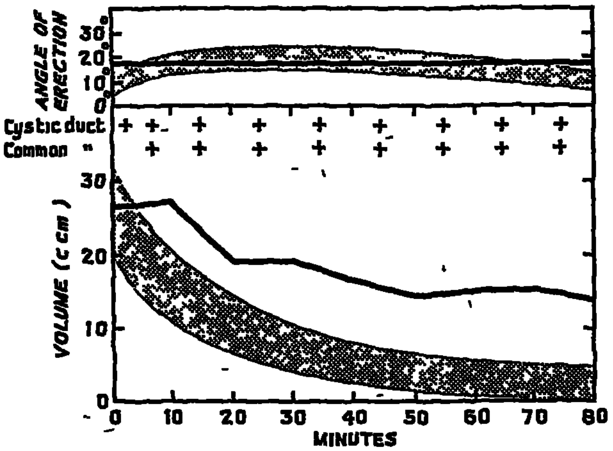

Fig 1—Serial cholecystogram, of case 1, showing a vesicular hypokinesia and a hypotonia The gallbladder is of normal size but evacuates insufficiently The angle of erection does not change throughout the examination The plus signs indicate visibility of a duct

Group IV Recurrence after a period of relief

Groups I and II are regarded as good results and III and IV as bad results

The following is a brief resumé of a typical case of hypotonic vesicular stasis

Case 1.—A woman, aged 32, weight $9^3/_4$ st *Dec 31, 1947* onset of fever (which lasted only two days), anorexia, nausea and vomiting, upper abdominal pain The liver was enlarged and tender A diagnosis of infective hepatitis was made

Jan 30, 1948 the symptoms persisted and she was readmitted, a diagnosis of duodenal ulcer was made, but the symptoms did not respond to the appropriate therapy

April 9, 1948 admitted to the teaching hospital when two other physicians and a surgeon were consulted and a diagnosis of subacute pancreatitis was made The symptoms continued, with progressive loss of weight

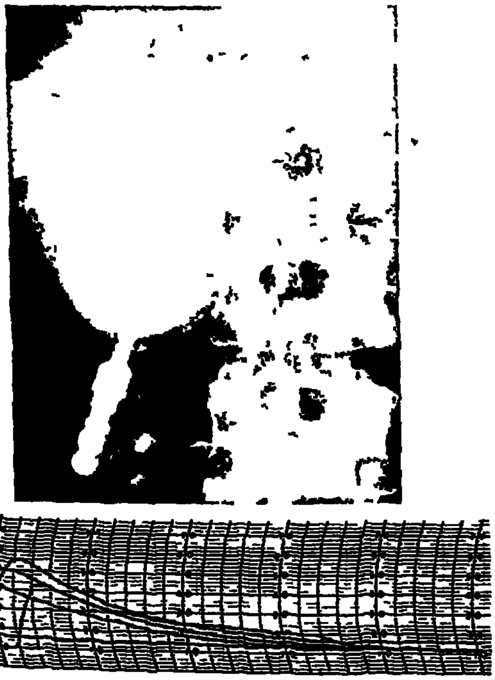

Fig 2—The operative cholecystocholangiogram of case 1, showing an atonic gallbladder with a sinuous common duct The manometric reading shows that the intravesicular pressure stabilised at 12 cm of water

July, 1948 there was a further acute attack, and readmission to hospital There was continuing loss of weight This time a pyloric ulcer was diagnosed, but this was not in accord with her symptoms Appendicectomy performed

Jan 9, 1949 referred to another teaching hospital with another acute attack of pain and dyspepsia, this time there was tenderness in the upper right abdomen and a marked intolerance of fats Weight was 7 st 6 lb After another negative cholecystogram, a second laparotomy was performed, when no abnormality other than adhesions was discovered The adhesions were divided The symptoms persisted but her weight remained at $7^1/_2$ st There were frequent migrainous bilious attacks

The patient left the district and was not seen again until *July 19, 1955*, when she returned with an acute attack of pain, one of many frequent recurring attacks There was obvious bilious pallor, tenderness below the right costal margin, and headaches At this stage the patient came under my care, a serial cholecystogram (fig 1) demonstrated vesicular stasis, probably of the primary hypotonic variety In *October, 1955*, the diagnosis was confirmed at operation (fig 2) and a right splanchnicectomy was performed

Now (two years after the operation) the patient has regained her lost weight and, apart from taking a little care with her diet, is perfectly restored to health and has taken up her full duties as a teacher She still has a few minor symptoms which in no way trouble her A further serial cholecystogram showed an improvement, but not a complete return to normal, in the motor function of the biliary tract

TABLE I—RESULTS FROM THE SURGICAL TREATMENT OF HYPOTONIC VESICULAR STASIS

Duration of follow-up (months)	Classification of results				
	Ia	Ib	II	III	IV
3					
3–6					
6–12	2		2		
12–24	9*	2	2	1	1
24–36					1†

* One of these patients had a cholecystitis only and a cholecystectomy only was performed

† This case is now recognised as one of a kink associated with a hypotonia, and has subsequently had a cholecystectomy with a good result

The condition was considerably improved by a right splanchnicectomy—so much so that the patient and her relations regard her as being cured, but as she still must take some care with her diet and must not overindulge in fats, and still has some minor symptoms, the result must be placed in group II

Table I shows the analysis of the results obtained from the surgical treatment of hypotonic vesicular stasis In the 20 cases operated on, 17 results can be regarded as good and 3 as bad There is not only symptomatic relief but also improvement in the motor function of the biliary tract in 5 cases repeat control cholecystograms were carried out several months after the operation, and in each there was an improvement in the evacuation curve, which, however, in no case returned to absolutely normal It seems reasonable, therefore, to attribute the symptomatic relief to an improvement in the function, and not, as critics have suggested, to the psychological effect of the treatment or to the enthusiasm of the doctors treating the patient[1]

In 13 of these cases of hypotonic vesicular stasis, there was no morphological abnormality, in 4 there were gallstones, in 2 a low-grade chronic cholecystitis, and in 1 cholesterosis 6 of these latter 7 cases had a cholecystectomy, and 1 had a cholecystlithotomy as well as the splanchnicectomy

Hypertonic Vesicular Stasis

Hypertonic vesicular stasis is a condition in which the gallbladder empties insufficiently on account of some obstruction to its evacuation, either functional or mechanical, and in which the intravesicular pressure is raised when it is measured by manometry at operation Of the 34 cases of vesicular stasis which form the basis of this paper 14 were of the hypertonic variety

The purely functional type is quite rare, and there were only 5 examples in this series In addition, in 2 cases there were duodenal ulcers This condition is caused by a spasm of the sphincter of Lutkens (1926) and also may be associated with a spasm of the sphincter of Oddi These spasms may be either primary (i e , no organic lesion can be demonstrated), or secondary to some organic lesion, such as a duodenal ulcer

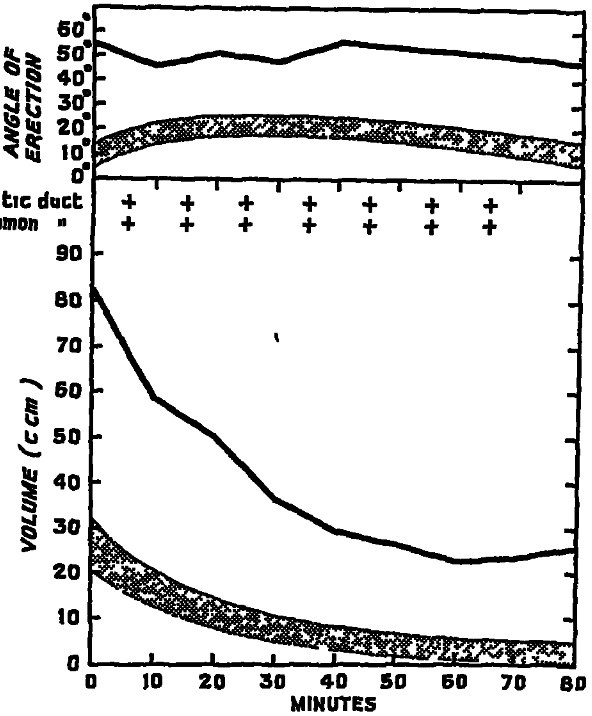

Fig 3—The serial cholecystogram of case 2, showing an abnormally large gallbladder which does not empty completely, with a high angle of erection The presumptive diagnosis is one of generalised biliary hypertonia

Clinically there is no clear-cut syndrome, and it is impossible to make an accurate diagnosis from the clinical history and physical examination alone There may be episodes of severe pain in the right hypochondrium, similar to attacks of gallstone colic, unaccompanied by an elevation of temperature Sometimes the pain is less precise and may even resemble that of a peptic ulcer Other patients complain of a typical biliary dyspepsia associated with headache and aggravated by fats Serial cholecystography shows a vesicular stasis with increased vesicular tone On the other hand, in longstanding cases a hyposystole may be present—i e , there is a slight initial contraction of the gallbladder which soon passes off Manometry at operation shows an intravesicular pressure which is above the normal of 18 cm and falls after the vagus is blocked with a local anæsthetic Radiography at operation shows a somewhat dilated gallbladder, a narrow cystic duct, and sometimes a common duct which ends like a well-sharpened pencil, indicating a coexisting spasm of the sphincter of Oddi

TABLE II—THE RESULTS OBTAINED FROM THE SURGICAL TREATMENT OF HYPERTONIC VESICULAR STASIS DUE TO SPASM OF THE SPHINCTER OF LÜTKENS

1 case of recurrent pancreatitis with obstruction of the sphincter of Oddi, due to a combination of spasm and fibrosis, was classified as a group Ia after 12 months

Medical treatment of this condition usually fails, though some temporary improvement can be obtained by the administration of spasmolytics The surgical treatment of the purely functional type of hypertonic vesicular stasis is

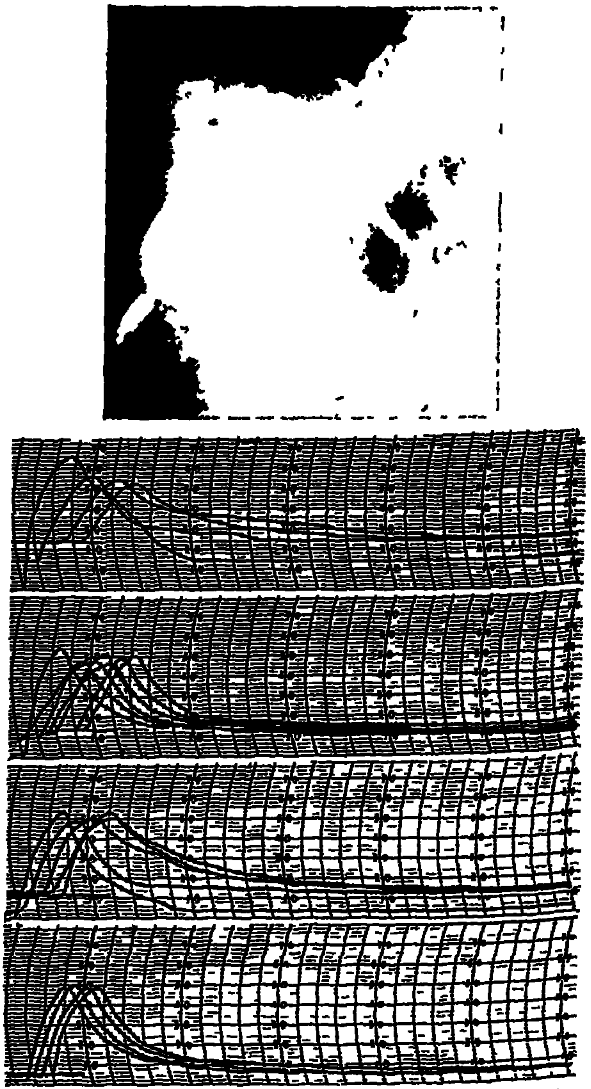

Fig 4—The operative cholecysto-cholangiogram of case 2, showing a pear-shaped gallbladder, a slightly narrowed common duct which is angulated, and a long reflux along the pancreatic duct The manometric readings show in the top graph a high intravesicular pressure, which stabilised at 24 cm of water; the second graph shows the pressure in the common duct, which stabilised at 14 cm of water The third and fourth graphs show that after blocking of the vagus the pressures stabilised at 12 cm and 6 cm. respectively, indicating a spasmodic hypertonia

to eliminate the spasm by vagal section or, as Mallet-Guy et al. (1947) advise, by cholecystectomy

Case 2.—A man, aged 43, had an eight-year history of dyspepsia, with pain across the upper abdomen radiating to both shoulders, to the left side of his chest, and into his back He had flatulence, nausea, and vomiting, which was aggravated by fatty foods Serial cholecystography (fig 3) showed a very large gallbladder which evacuated imperfectly with a high angle of erection. The presumptive diagnosis was a generalised biliary hypertonia

At operation, the gallbladder was large but otherwise appeared normal The intravesicular pressure stabilised at 24 cm of water The cholecysto-cholangiogram showed a narrow common duct and a long reflux along the pancreatic duct. The pressure within the common duct stabilised at 14 cm of water After the vagus had been blocked with local anaesthetic, the pressures stabilised at 12 cm and 6 cm respectively A diagnosis was made of spasm of both the sphincters of Lütkens and Oddi (fig 4)

A low vagotomy was performed. More than a year after his operation, the patient remains completely cured

The results of the surgical treatment of these cases are shown in detail in table II To sum up, in the 5 cases of pure spasm of the sphincter of Lütkens, good results were obtained, and both the patients with an associated duodenal ulcer were completely cured, by a vagotomy and posterior gastroenterostomy There was in addition 1 case of vesicular stasis associated with a recurring pancreatitis and an obstruction to the sphincter of Oddi by a combination of spasm and fibrosis, cholecystectomy, vagotomy, and sphincterotomy were performed, with a complete cure

A hypertonic vesicular stasis may be caused by a valve-like anatomical abnormality in the region of the junction between the cystic duct and the gallbladder This condition was first described by Schmeiden in 1920 These valve-like peculiarities and certain dysplasias of the neck of the gallbladder and the infundibulum give rise to intermittent obstruction to the evacuation of the gallbladder, which is followed by dilatation, angulation, and further obstruction The gallbladder may be divided anatomically into the fundus, the body, the neck, and the infundibulum, which leads into the cystic duct (fig 5)

It is very difficult to differentiate a valve-like deformity from a pronounced kink in the infundibulocolic region of the gallbladder, and it may be impossible to say whether a particular specimen should be classified as a valve or as a kink Such a deformity can be associated with a generalised biliary hypotonia It was thought, however, that these abnormalities should be discussed with the other causes of hypertonic vesicular stasis There is another somewhat ill-defined group of conditions which Guy Albot (1953) and his associates call infundibulo-colo-cysticitis, in which they include the various dysplasias other than kinks, valves, and acute inflammations This is a form of the so-called chronic cholecystitis which is localised to the infundibulum and neck of the gallbladder and a fibrotic condition of the cystic duct

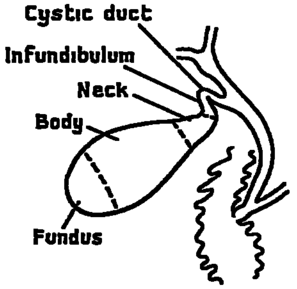

Fig 5—Anatomical regions of the gallbladder

The clinical signs and symptoms and the cholecystographic findings are variable and depend on whether the gallbladder is able to contract forcibly against the obstruction or whether the contractile power of the gallbladder has failed and a state of atony exists The most commonly found (and relatively early) condition is one in which the gallbladder still retains its power to contract. The patient complains of severe attacks of pain of short duration brought on by fatty foods Between attacks there is usually comparative freedom from pain In the early stages of this condition the serial cholecystogram shows a gallbladder which evacuates, insufficiently, with an increase in tone and contraction In most cases there is an obvious kink in the infundibulo-colic region, usually best seen on the lateral views (fig 6), but sometimes more distinctly seen on the anteroposterior view (fig 7)

Eventually the gallbladder loses its power to contract effectively against the obstruction In this late stage the

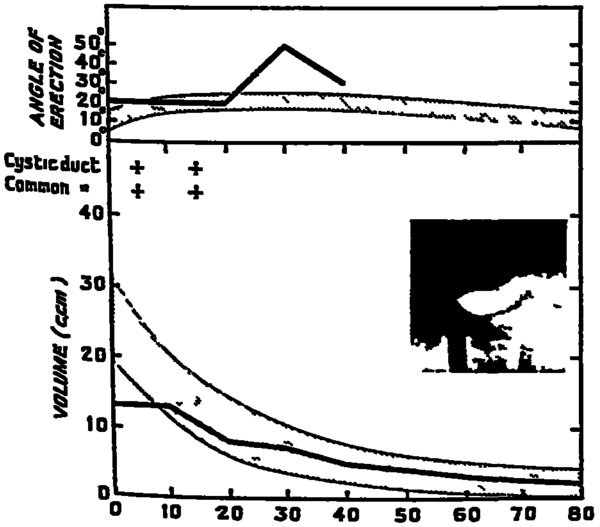

Fig 6—Serial cholecystogram, showing a small gallbladder which evacuates insufficiently, with an angle of erection which rises sharply late in the examination. The inset, a lateral view of the gallbladder shows a marked kink in the infundibulo-colic region of the gallbladder A presumptive diagnosis was made of vesicular hypokinesia associated with a kink.

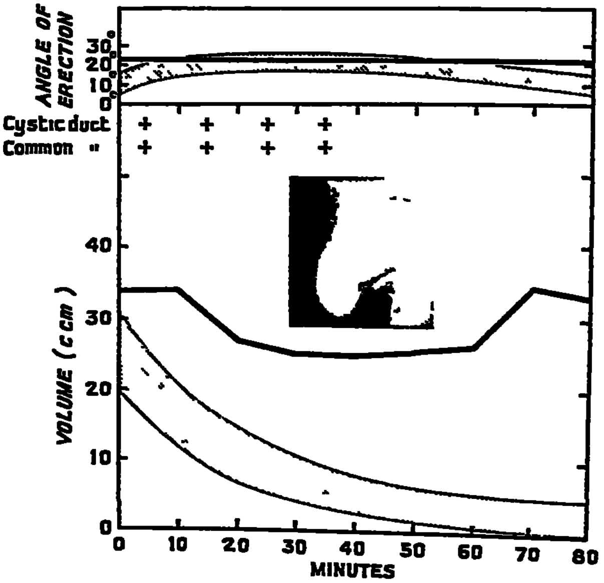

Fig 7—The serial cholecystogram of case 3, showing a vesicular hypokinesia and hypotonia associated with a kink in the infundibulo-colic region (demonstrated on the anteroposterior view) A presumptive diagnosis was made of vesicular hypotonia and hypokinesia associated with a kink.

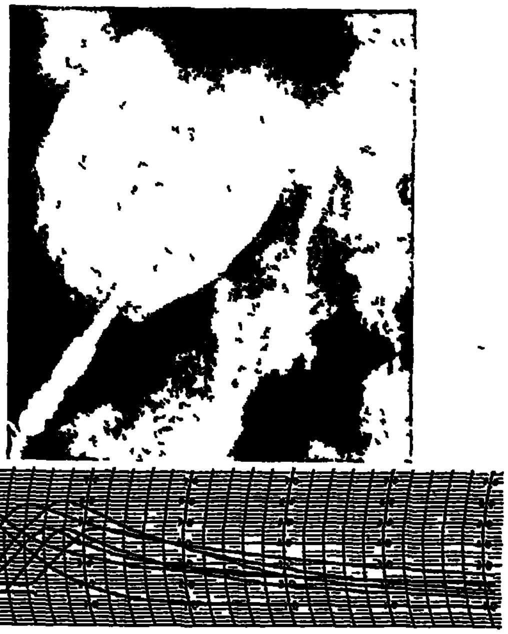

Fig 8—Operative cholecysto-cholangiogram of case 3, which shows a gallbladder slightly larger than normal, a marked infundibulo-colic kink, a long spiral valve, and a widely patent sphincter of Oddi Manometric readings show an intravesicular pressure which rose to 24 cm of water and fell to stabilise at 15 cm of water, indicating a biliary hypotonia associated with an infundibulo-colic kink

attacks of pain are replaced by a dull ache, more constant in character, in the epigastrium and radiating to the back Cholecystographically the gallbladder is atonic It is impossible as a rule at this stage to differentiate this condition from a primary hypotonic stasis This differentiation can be made only by manometry at operation (or trans-parieto-hepatic puncture of the gallbladder) In this series there were 6 patients with a valve or kink, one of which was associated with a gallstone

In the cases of a cystic valve and of infundibulo-colocysticitis, the pressure within the gallbladder is typically higher than normal and is not reduced by blocking the vagus The pressure curve of the infundibulo-colic kink is also quite characteristic in this condition the pressure curve rises to a certain level and then suddenly drops to a lower level, where it stabilises The peroperative radiographs often show a well-defined kink or tortuosity in the infundibulo-colic region The treatment of these cases is cholecystectomy, supplemented by the correction of any dystonia of the common duct which may be present

Case 3 —A woman, aged 45, had a fifteen months' history of painful dyspepsia with nausea and vomiting The pain was in the epigastrium and below the right costal margin, and radiated to both shoulders She had severe headaches with the dyspepsia, which was aggravated by fatty foods Serial cholecystography (fig 6) showed a gallbladder slightly larger than normal with gross insufficiency of evacuation The angle of erection was slightly higher than normal but did not increase during the test An obvious infundibulo-colic kink was demonstrated A presumptive diagnosis was made of a hypertonic vesicular stasis

TABLE III—RESULTS OBTAINED FROM THE SURGICAL TREATMENT OF HYPERTONIC VESICULAR STASIS DUE TO A VALVE OR AN INFUNDIBULO-COLIC KINK

Duration of follow-up (months)	Classification of results				
	Ia	Ib	II	III	IV
3			1		
3–6					
6–12	1	1			
12–24	3	1			

At operation, there were many adhesions between the under surface of the gallbladder and the surrounding viscera, these were especially dense in the region of the neck The intra vesicular pressure rose to 23 cm of water and then stabilised at 15 cm of water

The cholecysto-cholangiogram showed an infundibulo-colic kink (fig 8) The pressure within the common duct stabilised at 10 cm of water

A cholecystectomy was performed After 21 months the patient is completely cured and no longer has severe headaches

Table III gives a detailed analysis of the results, in brief all 7 patients obtained good results In 1 case there was a generalised biliary hypotonia, and a right splanchnicectomy was performed in addition to a cholecystectomy

On rare occasions a very small stone may be found in the cystic duct, causing an incomplete obstruction of the duct and thus leading to a hypertonic vesicular stasis If the obstruction is complete there will be an exclusion of the gallbladder and no gallbladder shadow on cholecystography

Summary and Conclusions

Vesicular stasis is a common disorder of the biliary tract, it was found in nearly a fifth of 200 consecutive patients who were investigated and treated There are two main types, the hypotonic and the hypertonic

The "classical" cholecystogram in this condition shows no abnormality, and an accurate diagnosis can only be made by means of serial cholecystography or trans-parieto-hepatic puncture of the gallbladder before operation, and by manometry and radiology at operation Of 34 cases of vesicular stasis treated surgically, the results were good in 31, only 3 remaining unimproved

ACROPARÆSTHESIA IN MYXŒDEMA

A CLINICAL AND ELECTROMYOGRAPHIC STUDY

I P C Murray

NEUROLOGIST IN CHARGE, NEUROLOGICAL UNIT, NORTHERN GENERAL HOSPITAL, EDINBURGH

Lethargy and slowness of movement are well known in myxœdema and widely accepted as manifestations of the effect of the hypothyroid state on the nervous system Paræsthesia, though less familiar, is mentioned by several authors (Williams 1950, Werner 1955, Soffer 1956) and nerve deafness has been described Nevertheless, no systematic clinical study of the neurological manifestations of myxœdema has been made, and the nature of many of these symptoms is assumed, without adequate evidence, to be the result of hypometabolism of the nervous system We report here clinical and experimental observations designed to test this hypothesis Preliminary results have been recorded (Murray and Simpson 1957)

Material and Methods

The present series comprises the first 35 patients observed in a general study of myxœdema

The diagnosis was made on the basis of the clinical findings, laboratory investigations, and results of therapy The tests used were estimations of the basal metabolic rate (B M R), the serum-cholesterol levels, and radio-iodine studies consisting of the measurement of the urinary excretion of radio-iodine over the first forty-eight hours and the uptake of radio-iodine by the thyroid gland over the first forty-eight hours after the dose had been given. A final diagnosis was made only after the responses of the clinical state, the B.M R , and the serum-cholesterol level to l-thyroxine sodium were known All the patients were observed for at least three months The cases were classified as minimal, mild, moderate, or severe on the basis of the general clinical picture and the B M R

11 patients were examined by an electromyographic method previously described (Simpson 1956)

The conduction velocity of the median and ulnar nerves was measured by recording the time delay of the muscle-action potential (of the abductor pollicis brevis and of the abductor digiti minimi muscles respectively) after supramaximal electrical stimulation of the nerve at elbow and wrist Coaxial needle-electrodes or silver-disc surface electrodes were used with conventional amplification and cathode-ray oscilloscope recording techniques The method and the type of record obtained are illustrated in the accompanying figure.

Results

Paræsthesia

Of the 35 consecutive patients 26 complained of paræsthesia of the fingers This was usually described as numbness or pins-and-needles and tended to occur either during certain activities—e.g , sewing, knitting, or washing clothes—or during the night, when the tingling was often sufficient to prevent sleep or to rouse the patient from sleep It was usually present on waking in the morning and passed off soon after rising Sometimes an " electric shock " sensation was noticed if an affected finger suddenly touched a hard object. Both hands were involved in 20 patients 17 patients stated that the little finger and sometimes also the ring finger were not affected by paræsthesia 7 described involvement of all their fingers, and 2 patients described numbness restricted to the ulnar side of the hand Motor symptoms were more difficult to assess Most of the patients described the clumsiness of manipulation which is well recognised in myxœdema, but 8 patients described marked loss of power of finger-thumb grip and wasting of the hand suggestive of genuine paresis Only 2 patients mentioned occasional tingling of the toes

Sensory Impairment

Evidence of sensory impairment was present in 8 cases 6 of these and 2 further cases without sensory loss showed muscle atrophy The sensory impairment was invariably on the radial side of the hand Appreciation of pinprick was reduced on the pads of the thumb, index, and middle fingers, and there was hypoæsthesia for cotton-wool on the same fingers and the radial half of the ring finger, sometimes extending proximally to the palm of the hand In 1 case the dorsum of the radial part of the hand was similarly affected, but in all the others the changes were confined to the palmar surfaces No demonstrable sensory changes were noted in the distribution area of the ulnar nerve

Motor Changes

The motor changes usually consisted in weakness and atrophy of the abductor pollicis brevis and the opponens pollicis muscles One patient had wasting of the first dorsal interosseous muscle of the right hand, and another had fasciculation of the flexor pollicis brevis All these muscles are wholly or in part supplied by the median nerve Thus all the objective sensory and motor findings pointed to a lesion of the median nerve

Electromyography

On electromyography with coaxial needle-electrodes the classical signs of partial denervation (spontaneous fibrillation and reduced motor-unit activity) were noted in 5 cases with objective weakness These manifestations were confined to the radial border of the thenar eminence, except in 1 case with fibrillation of the first dorsal interosseous muscle, which sometimes receives fibres from the median nerve (Rowntree 1949)

Conduction Velocity

Conduction velocity determined by the method described was examined in 11 cases (table I) One of these, case 1, is also case 15 of the original report on this method (Simpson 1956) Table I shows that the conduction-time of the median nerve was much increased in 3 cases, and that this increase was always due to a delay peripheral to the wrist-stimulating cathode. (The conduction-time between the two points on the nerve, obtained by subtraction, was normal in every case) In 4 other cases the conduction-time in the distal part of the median nerve was a little longer than is found in normal subjects, but the equipment used in the present work did not allow for measurement to an accuracy greater than 1 msec However, it is important to state that no unusual retardation was ever detected in the ulnar nerve, even in the first 3 cases mentioned

Carpal-tunnel Syndrome

The clinical and electromyographic findings indicate that the neuropathy is restricted to that part of the median nerve distal to the wrist, comparable in every way to the common carpal-tunnel syndrome In 1 patient acroparæsthesia of the right hand was promptly relieved by division of the flexor retinaculum six months before myxœdema was recognised When we examined her, she had moderate myxœdema Weakness of her right abductor pollicis brevis was still present She had recently begun to complain of tingling of the finger-tips of her left hand at night. No objective clinical or electromyographic changes were found The symptoms disappeared when her myxœdema responded to treatment

TABLE I—CONDUCTION VELOCITY

Case no.	Length* (cm)		Delay † (msec.)		Difference (elbow to wrist) (msec.)	Electromyography	Paræsthesia
	Elbow	Wrist	Elbow to muscle	Wrist to muscle			
1	30	6	20	14	6	Denervation	+
2	26 5	4 5	21	16	5	"	+
3	33	6	18	12	6	"	−
4	28	5	12	6	6	"	−

11	27	6	9	4	5	"	−

* Length measured from centre of stimulating cathode on median nerve to proximal recording electrode on abductor pollicis brevis muscle

† Time interval from stimulus to nerve to onset of action potential in muscle. Normal range elbow 8–12 msec., wrist 3–5 msec.

Relation of Neuropathy to Severity of Myxœdema

No correlation was noticed between the presence of neuropathy and the severity of the myxœdema Indeed many patients with neuropathy were only considered to have mild myxœdema, whereas the most severely myxœdematous patient in the whole series had no neuropathy On the other hand, a clear relationship was established between the clinical response to treatment of the myxœdema and the disappearance of the acroparæsthesia

Follow-up

At the most recent survey 30 of the 35 patients had become euthyroid Only 3 of these 30 still noticed occasional nocturnal paræsthesia 1 had atrophy of the thenar muscles, and this was unchanged The 27 others were normal 4 patients were still graded as "mild myxœdema" 1 of these had no change in the acroparæsthesia, the 3 others still had it occasionally 1 case was still considered to be "moderately severe", with acroparæsthesia unchanged

TABLE II—RELATION OF BODY-WEIGHT TO ACROPARÆSTHESIA

Case no	Weight (kg)	Change in weight	B M R (%)	Acro-par-æsthesia	Comment
12	77 8 70 5 75 0 67 0	−7 3 +4 5 −8 0	−31 +12 − 9 +21	++ − + −	Myxœdema relapsed when treatment was changed, with transient return of acroparæsthesia
2	77 3 68 7	−8 6	−36 − 2	++ −	Complete remission and restoration of conduction velocity (table III)
13	81 4 75 0	−6 4	−26 + 1	++ −	Rapid response to triiodothyronine (3 weeks), no relapse
6	63 6 61 8	−1 8	−28 − 3	− −	Severe myxœdema, but patient not overweight
4	85 0 82 7	−2 3	− 5 +21	++ +	Good metabolic response but remains overweight
8	68 2 67 2	−1 0	−30 − 8	+ +	Ditto
14	78 6 72 7	−5 9	−17 + 3	++ +	Ditto
15	64 0 66 3	+2 3	− −	+ +	Myxœdema improved, but patient gained weight

One of the histories is particularly interesting (table II, case 12)

Bilateral median paræsthesia had been very persistent in a woman with moderate myxœdema When this was treated with triiodothyronine, the neuropathy disappeared When treatment was changed to thyroxine, she had a temporary relapse, during which paræsthesia returned, but it finally disappeared when control of myxœdema was regained

Body-weight

The patient's weight appears to us to be of greater significance than the degree of hypothyroidism Selected cases illustrating this trend are shown in table II, which shows that severe myxœdema without excessive body-weight is not accompanied by acroparæsthesia (case 6), whereas very slightly myxœdematous patients have this symptom if they are overweight (case 4), and good metabolic response to treatment is not associated with recovery from acroparæsthesia if there is not significant loss of weight (cases 4, 8, and 14) One man (case 13) with severe myxœdema and bilateral median paræsthesia, with clumsiness of the hands, lost 6 4 kg weight in three weeks when treated intensively with triiodothyronine Within that period his paræsthesiæ disappeared and have not returned

TABLE III—RESTORATION OF NERVE-CONDUCTION VELOCITY

Date	Weight (kg)	Length (cm)		Delay (msec)		Difference (elbow to wrist) (msec)
		Elbow	Wrist	Elbow to muscle	Wrist to muscle	
Aug 21, 1956	77 2	26 5	4 5	21	16	5
Jan 23, 1957	68 6	25 5	5	12	7 5	4 5

Case 2 before and after treatment Recovery of conduction velocity is not yet complete

Restoration of Nerve-conduction Velocity

This was seen in one of the most severely affected patients (case 2)

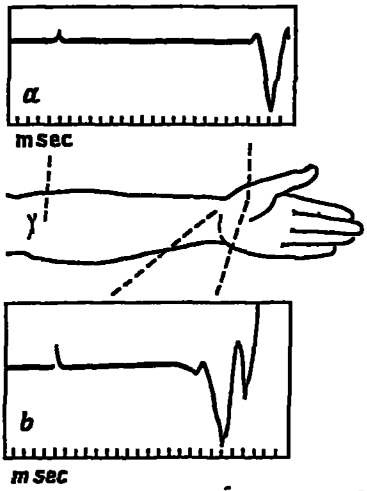
The patient, a woman with "moderately severe" myxœdema, had bilateral paræsthesia and sensory loss of median distribution in her right hand Movements of her thumbs were clumsy but quite powerful No obvious wasting was present, but electromyography disclosed partial denervation of the right abductor pollicis brevis muscle Conduction velocity of the right median nerve distal to the proximal palmar crease was greatly diminished, though the velocity above this point was normal (table I) Treatment with thyroxine achieved clinical cure of myxœdema, the patient lost 8 6 kg, the median-nerve symptoms disappeared, and the conduction velocity returned to normal (table III)

Discussion

Peripheral-nerve disorders in myxœdema are not widely recognised The standard textbooks on neurology (Wilson 1955, Brain 1955) list myxœdema among the causes of peripheral neuritis, but no references to original papers are given, and it is not clear whether the tabulation represents the personal experience of the writers From the context it appears that generalised peripheral neuritis is intended rather than the more restricted syndrome termed "acroparæsthesia", which is, by usage, confined to paræsthesiæ of the hands (Kremer et al 1953) Paræsthesiæ of the hands in myxœdematous patients have been mentioned by some workers (Williams 1950, Werner 1955, Soffer 1956) but have not been studied in detail

The diagnosis is doubtful in the 2 cases reported by Currier and Brink (1948) to show correlation between multiple neuritis and hypothyroidism

Their first case developed a neuropathy ten years after thyroidectomy The B M R was −27%, but the blood-cholesterol was 80 mg per 100 ml, there was also a history of macrocytic anæmia Free HCl was present in the gastric juice, but steatorrhœa was not excluded Treatment with thyroid extract caused "little change", but there was delayed improvement In their second case myxœdema was diagnosed despite a B M R of −8%, because the yellow colour of the patient's hands was considered characteristic of carotenæmia, which earlier workers (cited by Currier and Brink) believed to indicate hypothyroidism This patient had an acute paresis of all limbs,



Case 3—Shock artefact shows time of stimulus at cathode on median nerve at *a*, elbow, *b*, wrist After delay due to conduction along nerve this is followed by muscle-action potential recorded by coaxial needle-electrode in abductor pollicis brevis muscle

with retention of tendon-reflexes and a zone of sensory deficit along the dorsal spine. This unusual syndrome was regarded by Currier and Brink as a manifestation of polyneuritis, but they admit that neither of their cases conforms to accepted criteria.

We have therefore searched for peripheral-nerve symptoms in all patients found to be myxœdematous. Few patients presented with it as their primary complaint, but it was spontaneously mentioned by several others. On questioning it became clear that in most of them the paræsthesiæ were indeed distressing, but the degree of disability was difficult to assess in view of the mental lethargy and the predominance of more troublesome complaints, such as intolerance of cold. The mental state also made the determination of sensory disturbances difficult in many patients.

Our interest was intensified by the fact that one of us was studying the effects of metabolic disturbances on nerve conduction in man. It seemed a reasonable hypothesis that some of the slowness and clumsiness of the patient with myxœdema might be due to diminution of the rate of conduction of the nerve impulse. We were aware of the work of Lambert et al. (1951) showing that the twitch of an indirectly stimulated muscle was greatly slowed in myxœdema, and that this was responsible for "pseudomyotonic" tendon-reflexes. These workers had reported that the action potential elicited reflexly by tapping a tendon appeared after a normal delay, suggesting that the reflex arc, and hence the nerve-fibres, conducted with normal velocity. These studies, however, were made on the lower limbs, and our preliminary clinical investigations suggested that changes appeared earliest in the upper limbs, if indeed they were not confined to them.

Our clinical investigation disclosed a high incidence of symptomatic disturbances and many demonstrable motor and sensory changes confined to the hands. Sensory loss occurred exclusively in the part of one or both hands supplied by the median nerve. Motor phenomena involved only muscles in the hand supplied completely or in part by the median nerve. A few patients complained of paræsthesiæ involving the ulnar part of the hand. It is impossible to be dogmatic about subjective phenomena, but it should be noted that similar complaints are common in the carpal-tunnel syndrome (Kremer et al. 1953).

The clinical findings thus indicated a lesion of the median nerve in its distal part in all respects similar to that recognised as the carpal-tunnel syndrome. It was therefore of interest to find that the electromyographic study revealed that some of these patients had slowing of conduction restricted to the most peripheral part of the median nerve but not involving the ulnar nerve. The changes are those described in the carpal-tunnel syndrome (Simpson 1956).

The original hypothesis of diminished conduction of nerve due to hypometabolism was not confirmed. For this reason it is of some importance to examine this unexpectedly high incidence of carpal-tunnel syndrome in myxœdema, particularly as it has been reported in other endocrine disturbances—e.g., acromegaly (Kellgren et al. 1952) and pregnancy (Kremer et al. 1953). Further evidence that metabolic change in the nerve does not provide an explanation is seen in the lack of correlation between acroparæsthesia and the severity of myxœdema and in the relief obtained by operation in one case. On the other hand, there is a strong possibility that the syndrome is related to weight gain, and hence presumably to myxœdematous tissue under the flexor retinaculum at the wrist. Similar accumulation of soft tissue (with the possible addition of bone in acromegaly) could be postulated in each of the endocrine causes of the syndrome.

Summary

Median-nerve acroparæsthesiæ and paresis are common in myxœdema.

There is no generalised abnormality of nerve conduction, but slowed conduction in median nerve at the wrist can often be demonstrated.

The clinical and experimental findings indicate compression of the median nerves in the carpal tunnels.

The paræsthesiæ and paresis are probably caused by accumulation of myxœdematous tissue under the flexor retinaculum of the wrist.

GRAVITATIONAL LEG ULCERS IN THE ELDERLY *

STANLEY RIVLIN
M.R.C.S.

SURGEON TO THE LONDON VARICOSE CLINIC

BOTH patients and their doctors tend to accept the presence of an ulcerated leg with a grim and determined stoicism born of years of unsuccessful treatment. In the elderly this attitude of mind may be so far fixed that the patient will not seek treatment again unless given the stimulus of renewed hope.

This paper is based on a study of 200 consecutive cases of gravitational ulceration, 93 of them in patients over 60 years of age. "Gravitational ulcer" is a generic term, devised by Dickson Wright (1931) to emphasise the production of œdema in the lower limb when the heart is at a higher level than the leg. For the leg to become œdematous, the patient does not have to be *erect*, as is sometimes supposed; a man sitting up in bed will not lose his pitting œdema, and it may not disappear even if he lies down. This is why so many ulcers fail to heal in bed. It is not until the foot of the bed is raised 9 in. (the patient lying flat with one pillow for the head) that the heart can be guaranteed to be below the level of the leg and a gravitational ulcer equally guaranteed to heal. But this is a method to be avoided, wherever possible, in the elderly.

Of the 200 ulcers, 150 (75%) were classified as varicose, 30 (15%) as post-thrombotic, and 20 (10%) as miscellaneous. Œdema is the common final cause in all three groups. Varicose veins produce œdema by an alteration in tissue-fluid hydrostatics due to an increase in average venular pressure (Rivlin 1956). So also does deep venous thrombosis. Miscellaneous ulcers arise in lower limbs whose œdema is due to the failure of weakened or poorly used calf muscles to maintain an adequate venous return (e.g., hemiplegia, rheumatoid arthritis, arthritis of hip and knee).

---

* Based on a paper read before the Medical Society for the Care of the Elderly, Oct. 12, 1957.

I should like to see inscribed over the portal of all varicose clinics the slogan *œdema rots*, for this is the clue to the healing of leg ulcers

Diagnosis

Accurate diagnosis is essential not only for prognosis but also to make possible a comparison of results from different centres Unfortunately there is tremendous variation in the criteria of diagnosis In busy clinics there is little time for history-taking and examination Ball and Phear (1957) reported no less than 16% of their leg ulcers as "cause unknown", while Dodd et al (1957), in the hospital records of 51 out of 174 patients, found no note as to *whether or not* there was a history of deep thrombosis

In the London Varicose Clinic, forty-five minutes per patient is allowed for the initial interview The history-taking alone may be very tedious, for many of these patients have a long and involved story to tell, but complete assessment is well worth while, for in almost every case it enables an accurate diagnosis to be made, the prognosis to be determined, and the patient told what the future holds Treatment sessions are held separately

I estimate that out of every ten gravitational ulcers about six are due to simple varicose veins, three to venous thrombosis, and one to impaired leg-muscle action, R A King (personal communication) agrees with these ratios, but Dodd et al (1957) assume "most cases" to be post-thrombotic in nature, while Ball and Phear (1957) find 32% to be varicose

Treatment

Since a chronic gravitational ulcer needs œdema for its perpetuation, all treatment must aim at abolishing œdema

Bed

The simplest and most direct way of banishing œdema is to tip the patient so that her legs are higher than her heart, and this method has to be used for those who cannot walk But unless there is continuous supervision by an enthusiastic physiotherapist who regards it as her duty to prevent her patient from stiffening up in bed, we are liable to end up with a healed ulcer in a desiccated mummy The patient too—aided by non-stupefying analgesics—must play her part, persevering with exercise *at the ankle-joints to revive calf-muscle action* This is far from "bed rest" indeed, the patient must work very hard Details must be strictly adhered to A patient is allowed out of bed *only* to the toilet—a quick visit to the closet generates less œdema than a struggle with a bedpan—and may sit up in bed *only* for meals, thereafter lying down immediately Apart from these five occasions she must lie with one pillow for the head She may lie in any attitude she pleases, provided that the foot of her bed is permanently raised on 9 in blocks

Having said this, I must add that I used this method in only 3 of the 200 cases 2 had severe rheumatoid arthritis and 1 hemiplegia It is of course *not* a simple method The patients have to be visited two or three times a week, they cannot work, their morale has to be maintained, and above all they learn very little that will help them in the future *In the elderly, moreover, it is* the very antithesis of modern functional reablement

Ambulation

Bandaging *alone* will not heal many ulcers, but ambulation will do so, provided the patient can walk in comfort This explains why faith-healers achieve occasional successes and also why some ulcers heal, without our help, when the local nerve-ending is destroyed, pain ceases, and ambulation is resumed It is also the basis of the 19th-century procedure of sectioning the saphenous-nerve, which at one time had quite a vogue (Hilton 1863)

Bandaging speeds up the healing process tremendously by taking up the slack left by the vanishing œdema and preventing its return in periods of inactivity, and for this reason bandaging is essential But it is ambulation, not the bandage, that heals the ulcer

Re-education

First and foremost therefore the emphasis in treatment is placed on ambulation and normal use of the limb We ask the patients, "Which do you prefer, walking or standing?" Without a moment's hesitation they reply "walking", and this is the key to their understanding of their own problem, for if they place a hand on their own calf while flexing and extending their ankle, they can immediately appreciate (as one explains it to them) that walking is more comfortable than standing because the action of the calf muscles pumps out some of the "swelling" from their leg From that point they can be led to see that walking will prevent their leg from becoming tight and swollen in the bandage We explain to them that rest does far more harm than good Sitting in a chair with the legs up on a stool *impairs* venous return and is harmful At this stage a further dawn of recognition takes place, and they say "It's a funny thing, I always felt that rest made my leg more uncomfortable, but everyone told me to do it so I thought it *must* be right"

And now comes the most difficult and yet the most vital step of all, namely to insist that lace-up shoes are worn *all* the time and slippers completely abandoned These patients nearly all wear slippers or loose open shoes in the house, and if possible, at work It must be drummed into them over and over again that unless they wear lace-up shoes walking does not give them anything like full ankle movement, and hence full venous return, and that consequently much of the benefit of the treatment will be lost Good shoes make all the difference between a comfortable and uncomfortable bandage, and consequently between a fully mobile and semi-invalid patient After this it is easy to make them move their ankles while sitting, to point out the disadvantage of sitting close to the fire (which most of them have discovered for themselves), to warn against sitting with the legs crossed (because this retards venous return), and to arrange for the foot of the bed to be raised 9 in *if the ulcer is post-thrombotic* Finally they are given a card with the rules

USE YOUR LEG NORMALLY WHILST
UNDER BANDAGE TREATMENT

1 *Avoid standing STILL Take a few steps whenever possible*
2 *Wear lace-up Shoes, never slippers, in the house If your feet feel hot and tired at the end of the day, change into another pair of SHOES not Slippers*
3 *Do NOT sit with your legs crossed*
4 *Do NOT sit with your legs out in front of you on a stool*
5 *Sit NORMALLY but move your ankles up and down (as if beating time to music) every now and again*
6 WALK AS MUCH AS YOU PLEASE
7 Do not sit close to the fire
8 Never bath in the morning—only at night
*9 Raise foot of bed on 9in blocks

**Strike out if this does not apply*

clearly printed on it, not only to remind themselves of their new mode of life, but also to confront their well-meaning friends who say "but surely you ought to be resting your bad leg"

The Bandage

Non-irritating

At first I followed Dickson Wright's (1929) advice and used 'Elastoplast', with success (Rivlin 1951) But if skin irritation is to be avoided, we need an adhesive bandage that will not provoke a reaction from the dermis 'Poroplast' (Scholl) is well on the way to being such a bandage But, so far as ulcerated legs are concerned, the porosity on which the manufacturers laid stress, has made comparatively little difference, because the ratio of skin pores to bandage pores is so overwhelming that the degree of ventilation provided can have little physiological effect When Russell and Thorne (1955) compared porous elastoplast with equally porous poroplast they obtained better results with the latter because it contained virtually none of the irritating resins or rubbers which produce skin reactions

Adhesive

In my view it is essential that leg bandages should be adhesive Ulcers can, of course, be healed with non-sticky bandages, but most patients find that the tendency to take a peep at the ulcer, and perhaps apply a favourite salve, is almost irresistible But what matters even more is that a large proportion of patients can never be trained (or only at great cost in energy and time) to bandage their own legs efficiently they may make a passable show at it, but they do not take up the slack of their vanishing œdema nearly as efficiently as a professionally applied flexible adhesive bandage Hence, if the bandage is non-adhesive, their ulcers heal far more slowly, and they are far more likely to become dispirited

Flexible or Elastic?

The difference between "flexible" and "elastic" adhesive bandages is one of degree only, but it is important "Elasticity" refers to "stretch and regain" properties, but in fact in elastic bandages the stretch is *greater* than the regain, and after a fortnight's wear—which is the standard time—the bandage is undoubtedly looser than when first applied, and does not take up the slack of the vanishing œdema Towards the end of its clinical life it is not completely efficient The "elastic" adhesive bandage is said to have a massaging action as the patient walks, but the "massage" comes from within, not from without The muscle movement requires only a moderate degree of "give" in the bandage, in other words it is the *flexible* adhesive bandage, which has a moderate degree of stretch and in fact is no looser at the end of a fortnight than when first applied, that possesses the most desirable qualities for bandaging ulcerated legs

Paste Under-bandage

At the London Varicose Clinic, local skin irritation has been much reduced since the introduction of Scholl's 3 in flexible adhesive bandage (poroplast) I now see only 3 cases of irritation and allergy each year, as opposed to 50 or 60 previously But I still use a paste under-bandage on the leg—for two reasons

1 With a paste bandage underneath, irritation is further lessened and can be spotted and dealt with long before any generalised allergic reaction takes place (A paste bandage does not protect a sensitive skin against bandages with irritating components, for these penetrate it)

2 I have a clinical impression that some ulcers heal even faster as a result of the ingredients embodied in the paste bandages—usually some combination of zinc paste and ichthammol, urethane, and calomine

I personally prefer the 'Dalzoband no 4' for ease of application, though I believe that other ichthammol bandages are just as efficient Unlike this, the unna's paste type of bandage dries very hard, producing uncomfortable ridges on the skin

Application of Bandages

The art of bandaging is learnt only by apprenticeship Ideally, bandage technicians for varicose clinics should be specifically trained, as are orthopædic plaster technicians at the moment. The following methods are now in use at the London Varicose Clinic

Paste Under-bandage (Dalzoband No 4—one bandage)

The paste bandage is applied in almost the same manner as a plaster-of-paris bandage, in that the ultimate aim is a *smooth* case (remember any ruckle will be bandaged into the limb) of equal thickness throughout, stretching from the bend of the knee to the base of the toes We prefer to start at the bend of the knee, bandaging clockwise irrespective of whether it is the right or left leg, *laying* the bandage gently on without any pressure whatever Each turn overlaps the previous one by at least a half its width so that the bandage nowhere appears transparent We do *not* (as the manufacturer directs) "let the bandage go where it wishes", but—with a persuasive hand pleating over any fullness in the turns—we guide it in a circular manner down the leg The circular turns continue around the ankle to the toes, eschewing the figure-of-eight, which is liable to produce local constriction

Flexible Adhesive Outer-bandage (Scholl's 3 in —one and a half bandages)

Before the top bandage is applied, a strip of the adhesive bandage must be laid along the front of the limb from tibial tubercle to toes (fig 1) If this is not done the edges of the turns of the top bandage will cut into the leg at the front of the ankle and over the shin, producing discomfort, limitation in walking, and œdema This bandage begins at the base of the toes and ends at the bend of the knee The circular turns are laid on *firmly* and *evenly*, each overlapping the next by just over a half The method of circumnavigating the ankle is important, for on this depends much of the comfort of the bandage arrange the turns so that the lower edge of the fifth turn lies exactly on the point of the heel (fig 2), and then make the lower edge of the *following* turn lie at the junction of the tendo achillis with the calcaneum Where the bandage does not fit, pinch it together and cut it off Then continue clockwise up the leg to the knee

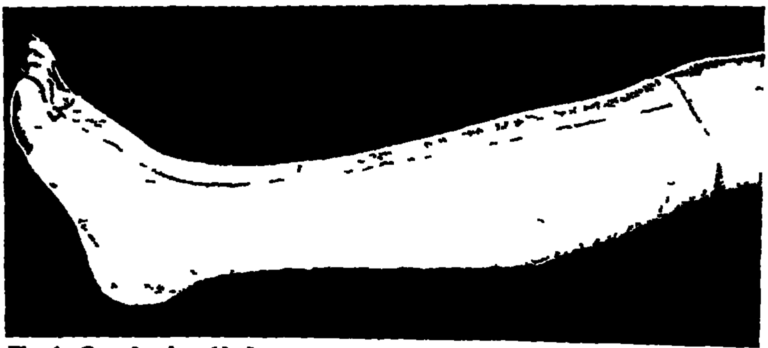

Fig 1—Completed ruckle-free paste under-bandage The longitudinal anterior strip of flexible adhesive bandage prevents the outer bandage from cutting in to ankle or shin

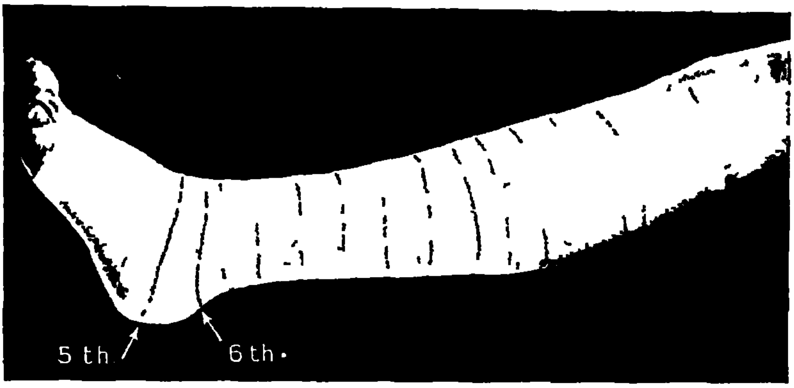

Fig. 2—Completed flexible adhesive outer bandage. Note method of circumnavigating ankle. The lower edge of the 5th turn is at the point of the heel, and the lower edge of the 6th at the insertion of the tendo Achillis.

Removal and Renewal

The first bandage should remain on for one week only, for this is the one that removes most of the œdema, and at the end of seven days it may be demonstrably looser than when first applied. For its removal we use special shears (Rivlin 1958), manufactured to our design by the Scholl Manufacturing Company. It is best to insert the shears under the bandage at the lateral border of the foot and cut along to reach the hollow behind the lateral malleolus, then cut up the lateral border of the leg along the muscular peroneal cushion, lifting the bandage off the skin as one cuts.

At the first removal we should see a leg virtually free of œdema, whose ulcer, if not smaller in area, is certainly more healthy-looking than a week previously, with a faint purple growing edge to its circumferential epithelium and early granulations within the formerly barren ulcer wastes. Continuation bandages should be applied as before until the ulcer is healed, remembering that the need now is probably not to squeeze out œdema but merely to hold the leg at its proper size. It is quite easy to overbandage legs, producing a thin pipe-like limb whose arterial inflow is undoubtedly disturbed. Unless patients are going on holiday, we make it a strict rule not to leave bandages on for more than a fortnight, otherwise autolysis from the ulcer discharge may cause local skin deterioration.

Results

In considering the immediate results of treatment three questions need answers:

1. How do the patients aged 60 and over compare with the younger ones?
2. Is there any outstanding difference in the speed of healing between the three groups of leg ulcers?
3. How rapidly can an ulcer be expected to heal?

On analysing the largest group, namely the *varicose* ulcers, we found that the average time of healing amounted to 10·2 weeks. The time averaged 11·5 weeks in those aged 60 and over and 9 weeks in the others (see table). But the average area of the ulcers when treatment was begun was over three times greater in the older than in the younger patients, and the rate of healing, expressed in square centimetres per fortnight, was three times greater in the elderly patients (see table). This accords with the suggestion that œdema causes gravitational ulceration, for, according to the clinical notes, œdema was far more pronounced in the older group—probably because the older patient has more opportunity and inclination to "rest". But, as soon as the œdema is banished, the ulcers heal as fast as in younger people.

RESULTS OF TREATMENT

Type of ulcer	Varicose			Post-thrombotic			Miscellaneous		
Age-group	20–59	60–90	All ages	20–59	60–90	All ages	20–59	60–90	All ages
No. of cases	77	73	150	22	8	30	9	11	20
Average healing-time (weeks)	9·0	11·5	10·2	11·2	15·0	12·8	10	16	13
Average size of ulcer (sq. cm.)	6·4	22·8	14·1	3·8	30·0	13·5	10	35	23·5
Average rate of healing (sq. cm. per fortnight)	1·2	3·6	2·6	0·7	4·0	2·1	2	5	4

In the case of the *post-thrombotic* and *miscellaneous* ulcers (see table), the ulcers in the older group remained under treatment longer, but again only because they were far larger to begin with. *Varicose* ulcers heal fastest of all.

Prevention of Recurrence

Briefly, the only ulcers that can really be cured are the varicose ulcers, but fortunately they form by far the largest group. A planned operation will rid these patients of their varicose veins, their tendency to gravitational œdema, and hence their ulceration. They need wear no form of support on their legs, can tear up their list of rules, and can behave as completely normal persons. Those who either do not wish to have an operation, or cannot have one, must be treated as the post-thrombotic group.

Ulcers of the post-thrombotic and miscellaneous groups cannot at present be fully cured although, of course, they can easily be healed, but an intelligent patient who understands the principles of œdema-prevention can keep his ulcer at bay without interfering very much with his normal life. He must keep faithfully to the rules, and *always* sleep with the foot of the bed raised 9 in. He should wear an elastic support on his legs. Neither elastic stockings nor the usual bandages are entirely satisfactory, but Messrs. Lastonet have produced a 5 in. × 7½ yd. (fully stretched) thin elastic net all-way stretch bandage† which moulds itself beautifully to the contours of the limb, is neither heavy, bulky, nor unsightly, and can be used for many months with frequent washing. Patients in the miscellaneous group must pay special attention to the re-education of the calf muscles.

Summary

The standard method of treatment at the London Varicose Clinic is described. Special importance is attached to the initial history and examination of the patient in order to classify the type of ulcer present as varicose, post-thrombotic, or miscellaneous.

Ambulation in proper footwear is by far the most important factor in treatment. Adhesive compression bandaging, using non-irritating materials, is ancillary to this but speeds up the rate of healing. Varicose ulcers can be expected to heal in ten weeks, post-thrombotic and miscellaneous ulcers in thirteen weeks. Instructions for applying bandages are given.

In the 200 consecutive cases of gravitational ulcer studied, elderly patients responded as rapidly to treatment as the younger ones.

True varicose ulcers can be cured by operation on the veins after the ulcer is healed. Post-thrombotic and miscellaneous ulcers can be kept at bay if the patient observes the principles of œdema prevention and venous return A new type of wide and light all-way-stretch supporting bandage is useful in the permanent aftercare of the post-thrombotic case

BLOOD-PRESSURE UNDER ANÆSTHESIA IN THE SITTING POSITION

VICTOR GOLDMAN

EASTMAN DENTAL HOSPITAL, LONDON

ONE of the main causes of brain damage or delayed recovery following dental anæsthesia may be its administration in the sitting position, according to Bourne (1957), who maintains that the blood-pressure may fall while nitrous oxide is being given, and that this indicates that the continued use of the sitting position for dental operations is unwise and likely to lead to permanent cerebral damage

Since the publication of Bourne's article we have recorded the blood-pressure of 100 unselected patients presenting unpremedicated at the Eastman Dental Hospital Their ages ranged from 5 to 65 years, and a breakdown of the cases into 5-year age-groups is shown in fig 1

Method

The blood-pressure was taken immediately after seating the patient in the chair and fixing the apron round his chest In each case the anæsthetic was administered by one of us, by a medical or a dental graduate, or by a medical undergraduate under supervision, with little or no variation in the results obtained by individual anæsthetists The operations lasted from one to eighteen minutes (fig 2) In the position adopted the patient sat with the seat of the chair tilting backwards but with the back-rest upright and the head-rest immediately under the occiput, so that he was in the "sniffing the morning air" position This is the position recommended for ease in nasal breathing

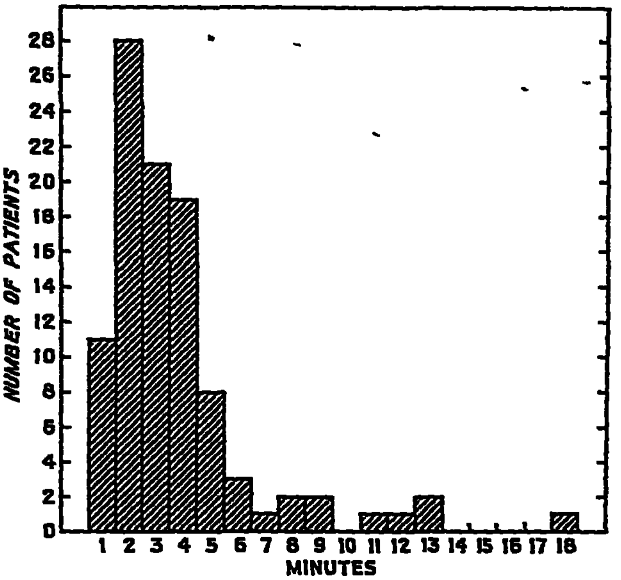

Fig 2—Duration of dental operation in 100 cases under general anæsthesia in the sitting position

The blood-pressure was taken at short intervals throughout the period of anæsthesia, five minutes after the patient had been removed from the dental chair to the recovery room in a wheel-chair, and again before the patient was allowed to leave the recovery room In all the cases the technique of induction was identical with that used and taught in this hospital for many years, and except in special cases, induction was with pure nitrous oxide until respiration became automatic, with inspiration shorter than expiration. At this point oxygen was administered to the patient, starting usually at about 8% and gradually increasing during the operation At the end of two minutes' operating the percentage of oxygen was usually increased to about 10%, and thenceforth by 1% at intervals of about a minute, even without any signs of anoxia During the whole operation an adequate and effective mouth pack was kept in situ to prevent both the inhalation of foreign bodies and dilution with air

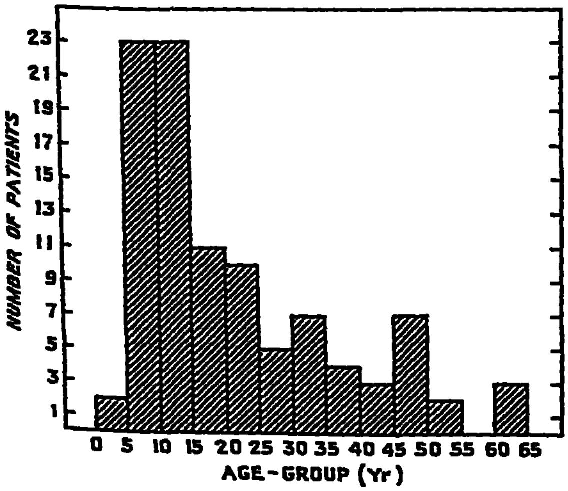

Fig 1—Age-distribution of 100 patients submitted to dental operations under general anæsthesia in the sitting position

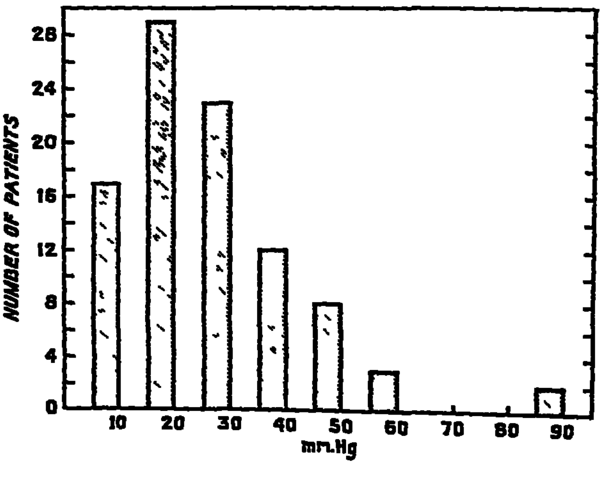

Fig 3—Amount of rise in systolic blood-pressure in 94 cases during administration of general anæsthetic with patient in the sitting position for dental operation

With this method of anæsthesia it was usual, at the end of five minutes' operating, for the patient to be receiving 12–14% of oxygen. If more extensive oral surgery was necessary and operating continued for more than ten minutes, the patient usually received 15%, 16%, or even 17% of oxygen with nitrous oxide. A rebreathing bag was not used unless the fractional rebreather on the McKesson machine was available, but in all the present cases no rebreathing bag was used, and consequently there was no retention of carbon dioxide.

The machines used were all tested on numerous occasions and gave oxygen percentages, under all conditions, within 1% of the amount indicated on the dial.

Results

In practically every case there was a rise above the initial blood-pressure. At the end of the period of anæsthesia, however, the blood-pressure fell, usually 5–10 m m Hg below the preoperative level, which might have been slightly raised through apprehension. It is, of course, impossible in these circumstances to get a blood-pressure reading under normal conditions without any stress or strain. However, in 94 cases systolic blood-pressure rose, at some point during the administration of the anæsthetic, above the preoperative and postoperative levels. The amounts of these rises are shown in fig 3.

21 of these patients had an initial rise of blood-pressure followed by a fall on the introduction of oxygen. In some cases the blood-pressure rose again, but at no time during the anæsthesia was the level lower than the postoperative reading.

In 9 cases there was an initial fall in blood-pressure after the start of the anæsthesia, but this level was not below the postoperative reading and was followed by a rise. These patients were usually excitable or very nervous.

In the remaining 64 cases there was an initial rise which was maintained throughout the period of anæsthesia.

In 6 cases the level of blood-pressure during anæsthesia was maintained steadily at the preoperative value, but the postoperative level in all cases was below this. The series included a child with a patent ductus arteriosus and a patient with a history of epilepsy. No delayed recovery or unusual effects were observed.

Discussion

It can therefore be assumed that the frequency with which syncope or fainting takes place under simple gas-oxygen anæsthesia is insufficient to cause great alarm, otherwise at least 1 case would have appeared in the present series, which included several lengthy operations.

This is a comforting thought because it confirms the safety of the practice of a hundred years' use of the sitting position, which in experienced hands does not increase the patient's risk of postoperative sequelæ. It is generally considered that the sitting position is the safest for dental operations in the absence of an endotracheal tube.

If, however, the sitting position had been shown to tend to produce complications, it would be necessary to operate on every patient supine. This would create a grave difficulty because, if more than four teeth were to be removed at one sitting, an endotracheal tube would be indicated in every case. Since about two million dental anæsthetics are given each year in the United Kingdom alone, this would mean a very great increase in the amount of work for hospitals and anæsthetists.

We hope that the result of our investigations will be accepted as proof that no special risk attends the routine that has been used for so many years, provided that nitrous oxide and oxygen are the sole anæsthetic agents used.

Summary

In 100 cases of dental extraction under nitrous oxide/oxygen anæsthesia there was an initial rise in blood-pressure above the preanæsthetic reading. This was usually maintained, but in some cases it fell with the introduction of oxygen, only to rise again to a level which was maintained to the end of the operation.

The blood-pressure fell to its preanæsthetic level or below within four minutes of the end of the administration of the anæsthetic agent.

No delayed recovery or untoward effects were observed.

OTALGIA WITH ŒSOPHAGEAL HIATUS HERNIA

W D F MALHERBE
M.B Cape Town
CLINICAL ASSISTANT, DEPARTMENT OF SURGERY,
UNIVERSITY OF AMSTERDAM (WILHELMINA GASTHUIS)

SINCE 1956 we have seen three patients with a combination of earache and abdominal symptoms.

Case-reports

Case 1.—A woman, aged 55, was admitted with epigastric discomfort immediately after meals—in no way related to the type of food—and occasional heartburn. Elsewhere she had been found to have a large stone in the gallbladder, and this was suggested as the cause of her symptoms. But, as she gave no history of colicky pains, and as on cholecystography the gallbladder concentrated the dye well, one hesitated to ascribe all her complaints to the solitary gallstone.

When a more detailed history was taken, she mentioned that for years she had had a painful, itchy sensation in the right ear. Sometimes this became intolerable, and could not be relieved by scratching the external auditory meatus. She had been examined by various ear, nose and throat (E N T) specialists, but no abnormality could be detected. After one such examination she had been given a prescription for bromide "for the nerves". When questioned further about her abdominal complaints, she gave the following significant answer: "I always have the sensation at mealtimes as if food sticks just here," and pointed to the lower sternum. "It is as if a bubble of air sticks here and troubles me. It then suddenly shoots through, giving immediate relief."

This aroused suspicion of an œsophageal hiatus hernia. Although the pain in the right ear was the chief complaint, the patient had mentioned this hesitantly because she thought it was completely unrelated to the abdominal symptoms for which she had been referred to the surgeon. Yet the ear symptoms can be logically explained by the presence of hiatus hernia. Although this combination of symptoms is not common, it is mentioned in the French literature. The stomach was therefore re-examined radiographically, but a hiatus hernia was not demonstrable in Trendelenburg position.

Cholecystectomy was decided upon. At laparotomy the presence of a solitary gallstone was confirmed, but the gallbladder appeared otherwise normal. The œsophageal hiatus, however, admitted four fingers with ease, and the cardiac end of the stomach could be made to slide up through the hiatus.

The hiatus was then narrowed by approximation of the crura posterior to the œsophagus until it admitted only one finger next to the œsophagus. Cholecystectomy was then performed. Finally the operative correction of the hiatus hernia was completed by gastropexy to the anterior abdominal wall (Boerema and Germs 1955, Boerema 1958).

For obvious reasons, we had refrained from telling the patient before operation that there could be a connection between the earache and the abdominal complaints. Immediately after operation she spontaneously volunteered that the pain in her ear had disappeared. She was much gratified, but rather surprised that the earache had disappeared after an operation through the abdomen! A year later she is symptom-free. The otalgia has not recurred.

Now on the alert for the presence of ear symptoms with hiatus hernia, we found two further cases

Case 2.—A rather obese woman, aged 75, was admitted with upper abdominal complaints of at least 30 years' standing She had burning pain in the epigastrium and behind the lower sternum after meals This radiated through to the back between the shoulder-blades She often had severe heartburn. All the symptoms were aggravated by lying down after meals On bending forwards she had regurgitation of acid food into the mouth With swallowing, food seemed to lodge behind the lower sternum, she had to "swallow twice" to get it down

For years she had had an unpleasant painful itching in the left ear This came on simultaneously with the pain behind the lower sternum.

On radiological examination of the œsophagus and stomach, a large "sliding" hiatus hernia was demonstrated, and, as she had been treated conservatively elsewhere without success, we decided to repair the hernia surgically At laparotomy the stomach was reduced into the abdomen. The hiatus was narrowed by approximation of the diaphragmatic crura behind the œsophagus, after which an anterior gastropexy was performed

Six months later she was symptom-free, having had no further pain in the ear

Case 3.—A very obese woman, aged 71, had had cholecystectomy elsewhere 18 months before She was well till about 10 months after the operation when she developed upper abdominal discomfort after meals, which was relieved only by vomiting The symptoms were aggravated by bending forwards, but not by lying down.

For some months she had also had an irritation in the throat, a sensation as if there was a "lump" in the throat which she could not swallow down At mealtimes, however, she had no difficulty in swallowing food. Associated with this discomfort in the throat, she had a painful, itchy sensation in the left ear She had been referred to an E.N.T. surgeon, who could find no abnormality in the ears, pharynx or larynx, and she had been reassured and given vitamin-B tablets

On radiography of the œsophagus and stomach, a large "sliding" hiatus hernia was found. which did not reduce in the erect position At least a third of the stomach was in the chest

She was put on a reducing diet with frequent small meals, and slept in an upright position. On this regime the abdominal discomfort diminished significantly, and the earache disappeared. With such marked improvement of the complaints we found operation on this elderly, obese woman not indicated for the present She was therefore discharged with instructions to follow the above regime

Discussion

Many workers have mentioned that the epigastric or substernal pain of œsophageal hiatus hernia may radiate through to the back, down the arms, or up to the base of the neck, and sometimes even to the mouth or to the angles of the jaw In the French literature radiation to the ears is also mentioned Hillemand and Wattebled (1953), Hillemand et al. (1954) Dubost and Blondeau (1956) emphasise that the disturbances caused by hiatus hernia may appear completely unrelated to the gastrointestinal tract, with the result that patients are referred to specialists in other fields Hiatus hernia may for instance cause precordial symptoms which closely simulate angina pectoris An apparently causeless secondary anæmia may exist, the hernia being discovered only after careful examination of the gastrointestinal tract. Reflex vagal disturbances may lead to crises of bradycardia with a fall in blood-pressure and loss of consciousness

Hiatus hernia may also present with pain in the ears This may be the chief symptom, as described in the first case The mechanism of its production can be explained anatomically

The vagus nerve, after leaving the skull through the middle compartment of the jugular foramen, gives off an auricular branch This enters a small foramen on the lateral wall of the jugular fossa and traverses a special canal, the mastoid canaliculus, in the mastoid part of the temporal bone It then divides into two branches which are distributed to the external auditory meatus and to a small area of skin over the mastoid process (Spalteholz 1921)

The vagus then passes down into the neck giving off its pharyngeal, laryngeal, and cardiac branches In the thorax it forms the pulmonary plexus for the supply of the lungs and the œsophageal plexus The œsophagus is supplied proximally by branches directly from the vagal trunk and distally by the œsophageal plexus

Gray's Anatomy (1946) described various "reflexes" in connection with branches of the vagus The "ear cough" is mentioned as one of the commonest. A plug of wax in the external auditory meatus may, by irritating the filaments of the auricular branch, be responsible for a persistent cough Syringing the auditory meatus may similarly produce coughing, or, in children, vomiting, moreover, syringing the ear has been responsible for a sudden fatal syncope, by reflex irritation of the cardiac branches Another common example quoted is the persistent cough which is common with enlarged bronchial lymph-glands in children, the irritation is referred to the superior laryngeal filaments

Reflexes in connection with the vagus and its auricular branch are therefore not uncommon. Similarly the phenomenon of otalgia with hiatus hernia can be explained as a referred pain along these vagus pathways Irritation of the œsophageal filaments produces stimuli which are centrally misinterpreted as coming from the auricular branch. Thus a painful itching in the ear results The vagus or its œsophageal branches may be irritated by pressure on the nerve in the hiatus, by stretching of the nerve over the hernial mass in the case of a large hernia or by periœsophageal inflammation where the hiatal hernia is complicated by œsophagitis

In the two cases where the hiatus hernia was surgically repaired the earache disappeared immediately after operation The irritation of the vagus nerve was therefore probably caused by a stretching or compression of the nerve by the hernia

Patients with a persistent, painful, itchy sensation in the external auditory meatus for which no local explanation can be found, and who may or may not have associated upper abdominal or substernal complaints, should therefore be examined for the presence of œsophageal hiatus hernia

Summary

Three cases are described in which œsophageal hiatus hernia was associated with pain in the ear The anatomical basis for this phenomenon is that both œsophagus and external auditory meatus are supplied by the vagus nerve, and the pain is probably referred The earache disappeared after effective treatment of the hernia

I wish to thank Prof I Boerema, head of the department of surgery, for encouragement and permission to publish these cases

CORTISONE IN THE TREATMENT OF ACUTE MILIARY TUBERCULOSIS

T A LAMBROS
M B Manc

LATELY HOUSE PHYSICIAN, GERIATRIC UNIT,
OLDHAM AND DISTRICT GENERAL HOSPITAL

> " Surely every medicine is an innovation and he that will not apply new remedies must expect new evils "
>
> FRANCIS BACON

YESTERDAY cortisone was considered to be contraindicated in tuberculosis, today considerable trials are being conducted using steroids in tuberculosis therapy The case presented is one thus treated

Case-report

A man, aged 64, had worked in an iron foundry for 36 years and latterly had been subject to mild bronchitis 4 years ago he retired from the foundry and took to " odd-jobbing " Just before Christmas, 1956, he worked 1 day in a local cotton-mill and then developed a " bad chest ", with left pleuritic pain and a cough He became feverish and was losing weight rapidly By Feb 7 he had taken to his bed, finally not eating or drinking and becoming confused

He attended the geriatric outpatient clinic on Feb 21, 1957, complaining of left chest pain, dyspnœa, cough, loss of appetite and of weight, sweating, and occasional vomiting He was somewhat confused and appeared very ill indeed He coughed day and night, with half a cup of yellow sputum a day, no hæmoptysis He was pale and wasted, temperature 100 4°F, pulse-rate (regular) 142 a minute, respiration-rate 28 a minute

His trachea was central, chest expansion fair and symmetrical, percussion-note resonant with slight impairment at the left base, and breath sounds vesicular with numerous medium rales, especially left base No abnormalities were found in other systems, apart from dulled level of consciousness

A provisional diagnosis was made of unresolved pneumonia with effusion or empyema, he was admitted His hæmoglobin was 64%, leucocyte-count 6400 per c mm, erythrocyte-sedimentation rate (E S R) 34 mm in the first hour He appeared to be dying and was considered unfit for X-ray screening Aureomycin was given

Over the next 5 days there was no change, the pyrexia continued The chest remained surprisingly quiet, with fewer moist sounds at bases than on admission The impairment at the left base had disappeared and a diagnostic pleurocentesis was not performed Sputum gave growth of normal flora Electrocardiogram normal A radiograph of the chest showed " extensive miliary mottling in all zones of both lung fields Appearances of miliary tuberculosis or pneumoconiosis " Examination of eyes showed a tubercle in the lower right conjunctival sac and two patches identical with miliary tubercle in the right fundus

Mantoux 1/10,000 was negative The cerebrospinal fluid (C S F) was opalescent, pressure 135 mm Protein 80 mg per 100 ml, globulin slight increase, Lange 1111100000, chlorides 565 mg per 100 ml, sugar less than 20 mg, cells 36 per c mm (polymorphs 50%, lymphocytes 50%) No organisms Wassermann reaction negative Culture yielded no growth Streptomycin 1 g b d and isoniazid 100 mg t d s started

On March 2 the Mantoux test was still negative After some slight initial improvement, the patient again appeared to be dying The dose of isoniazid was increased to 100 mg 6-hourly and cortisone acetate 25 mg q d s was begun At this stage his weight was 8 stone

After a few days he began taking some food and his condition improved slowly, but later more rapidly Streptomycin was reduced to 0 5 g b d The C S F contained protein 44 mg per 100 ml, sugar 49 mg, cells 72 per c mm (polymorphs 40%, lymphocytes 60%) Guineapig inoculation was negative

5 weeks after admission weight 9 stone On the chest radiograph, " miliary nodulation, though still extensive, appears less accentuated " E S R 50 mm in the first hour

By April 14 he was very much better The cortisone had been gradually discontinued Mantoux 1/10,000 became positive 24-hour specimens of urine and sputum throughout yielded no acid-fast bacilli The E S R remained raised

On June 6, the chest radiograph showed " very marked improvement, especially compared with original films Still faint reticulation and residual fibrosis at both bases " Later in June his weight was 10 stone, his E S R fell, and he was allowed home but continuing therapy The streptomycin and isoniazid were finally discontinued in August

In September the chest radiograph continued " to show improvement with some residual fibrosis " He is still under outpatient observation and remains very well

Discussion

This man, originally Mantoux-negative, had had mild chronic bronchitis for years after a lifetime in an iron foundry There is, therefore, the possibility of some degree of pneumoconiosis, and this is supported by the chest radiographs The later films show a fine reticulation which could be a reaction to dust or a streptomycin-treated-tuberculosis pattern He gave a vague history of having had " pneumonia " several times in 1950, but was treated at home and never radiographed

Although acid-fast bacilli were never isolated from his sputum, urine, or C S F, the response to streptomycin and isoniazid, together with the radiological picture of his chest, justify a diagnosis of miliary tuberculosis The fact that his Mantoux later became positive is also evidence in favour of such a diagnosis, though tuberculin sensitivity is occasionally depressed in acute stages of the illness The diagnosis of pneumoconiosis alone is excluded by the clinical picture and the final response to the therapeutic measures taken Until recent years acute miliary tuberculosis was considered a disease of young people, but more cases are now being reported in older ones

There were no physical signs of meningitis, except the abnormalities in the C S F, hence intrathecal therapy was not given, in the belief that isoniazid, given orally, freely enters the C S F, and that this would be sufficient in this particular case

Because of the ability of cortisone to alter fibrinogenesis and thus prevent the formation of adhesions, it is being used in tuberculous meningitis in many centres (Shane and Reilly 1953, Ashby and Grant 1955) Wasz-Höckert (1954) describes corticosteroids as " routine " in the treatment of tuberculous meningitis in Helsinki Choremis et al (1957) have used similar treatment in children All believe that cortisone has a definite beneficial effect on the clinical course and final result

When cortisone is used, the appropriate antimicrobial therapy must be given It is most useful in overwhelming toxic states, where immediate improvement of the patient's condition is imperative Cortisone does not interfere with phagocytosis, but deprives the monocytes of much of their capacity to inhibit the intracellular accumulation of bacilli (Lurie 1957) The result, therefore, is more primary tubercles, which are small and incompletely caseous, swarming with bacilli, with very little interstitial reaction

Lurie has pointed out that cortisone, by virtue of its anti-inflammatory effect, greatly hinders lymphogenous and hæmatogenous dissemination of bacilli When tuberculosis spreads under the influence of cortisone it does so by contiguity, with the movement of tuberculous macrophages

Shmelev (1957) has shown that cortisone given in the initial stages of disseminated tuberculosis can decrease the number and size of foci, reducing the exudative reaction, and that using cortisone with antituberculous drugs gives a better therapeutic effect than using antituberculous drugs alone

McLeod Riggins (1957) says that cortisone in tuberculosis has a threefold effect (1) anti-inflammatory (whether useful or not?), (2) anti-allergic (partial suppression of the hypersensitive state, which may be useful in various forms of acute tuberculosis), and (3) therapeutic, especially if tuberculosis is complicated by adrenocortical insufficiency In this case cortisone was administered initially for the last effect—as a " tonic " The patient appeared to be dying and it was felt cortisone might just turn the scale

Pharmacological, and not toxic, doses must be used, for the danger of hypercorticism is real, and the suppression of adrenocortical function, when cortisone is stopped after a long course, may not only produce addisonian symptoms but also reduce resistance to infection

Chenebault (1957) reported a series of 117 varied cases of tuberculosis which he treated with cortisone or allied steroids Spectacular results were seen in the miliary cases in 5 to 6 weeks Moribund patients became convalescent in 6 weeks Radiological improvement was "extraordinary", with an equally rapid general transformation

In conclusion, as always when spectacular results are reported, caution is very necessary As Kaufmann (1957) says, cortisone treatment is indicated particularly in patients with a toxic course and in those with a tendency to excessive mesenchymal defence reaction A careful selection of patients is indispensable

Summary

A man of 64 appeared moribund from miliary tuberculosis When given cortisone (in conjunction with streptomycin and isoniazid) he improved strikingly, and later he was discharged fit

Cortisone is indicated in selected cases of tuberculosis, where the course is toxic or the mesenchymal reaction excessive Antituberculous drugs must be given as well

I am grateful to Dr W H Lloyd, consultant geriatrician, for permission to publish this case and for the encouragement he has given me throughout I also want to thank Dr D Plowman and Dr T D O'Brien (registrars in the geriatric unit), Dr D A H Walton, Dr E Ratner, Dr C H Adderley, and Dr L B Hardman

New Inventions

BED WITH BEDPAN

THE bedpan, as ordinarily used, has many disadvantages, and patients have expressed approval of a bed which I have designed to overcome some of the objections

A standard type of hospital bed is modified so that part of the frame containing the mattress is extensible (fig 1) Beneath the mattress, resting in a light metal frame, is a movable tray which can be raised to the level of the mattress by means of two arms on either side The tray contains the bedpan, which can be easily inserted or removed by means of a movable handle when not in use, this is flush with the surface of the tray When the bedpan is needed, the slots at the foot of the bed are opened, and this allows the movable part of the frame to be extended When it has been extended enough to clear the underlying tray (fig 2), the screw on the side of the movable part of the frame is tightened to prevent further extension The tray containing the bedpan is then raised into position so that it comes to rest at the level of the top of the mattress (fig 3) and the patient can now slide on to the seat

If necessary, the locking screw may be released and the bed further extended to allow the patient's feet to come down to the floor, enabling him to assume the correct position for defæcation When the pan has been used the legs are raised by nurses and placed on the mattress The screw is released and the frame partially closed, the screw is then tightened and the patient slides back on to the bed

A lid is applied to the receptacle, which is lifted out of the tray, the tray is then lowered The lock holding the movable part of the frame in position is then released, the bed is closed, and finally the slots at the foot of the bed are shut Nurses have found the bed easy to work, but in the prototype the tray has proved rather heavy Further improvements suggested are a lighter tray, made from aluminium and covered with 'Formica' or polyethylene, and a plastic receptacle, which should have a spout anteriorly instead of being circular

A standard hospital bed of this type has been modified by Messrs James Sherret and Sons, Brechin

Stracathro Hospital,
Brechin, Angus

Reviews of Books

Australia in the War of 1939–1945

Medical Series The Island Campaigns ALLAN S WALKER, M D, CH M, F R A C P Canberra Australian War Memorial London Angus & Robertson 1958 Pp 426 35*s*

OUR soldiers in Burma talked of themselves as "forgotten men", but some of them who heard the late Brigadier J A Sinton, V C, on the Australian conquest of malaria realised at the time how little they knew of the even less publicised war in New Guinea and the near-by islands The conditions, climatic and geographical, were not unlike those in northern Burma heavy rainfall, flooded rivers, lack of roads—and malaria No-one has yet written a connected account of the work done by Sir Neil Hamilton Fairley and his associates on experimental malaria and the applications of their results to an army fighting a mobile war in an area where malaria is hyperendemic Public imagination was stirred by the patient and inconspicuous work which gave us better weapons of war, but if ever a war was won "out of sight" it was at Cairns Since then the methods have been improved, and in peace it is generally true that it is poverty rather than ignorance which allows malaria to survive This book has much to say of Fairley's work in the laboratory and in the field, but because it is a chronological account of the medical services in campaigns often fought simultaneously the account is disconnected

Because of the similarity in conditions, the book will be of most interest to those who fought in Burma, but there were some obvious differences Air support and supply seem to have been on a smaller scale in the islands, but far more use could be made of the sea the natives were more numerous and usually friendly and helpful the numbers engaged were less and there was no big battle comparable with the crossing of the Irrawaddy Both were junior officers' wars in which success and failure were obvious to everyone In both there was general agreement on the main problems of military medicine forward surgery followed by quick evacuation of the wounded, the malarious to be held near the line until fit for duty, preventive medicine not the responsibility of the "sanitary squad" but of every man in every rank

This is a very interesting book but not an easy one to read It seems that every medical participant is mentioned by name, each stage of evacuation is detailed at every point, and every move of each field ambulance is marked on the map For those who fought elsewhere the book would be better for wider survey of the campaign Pictures and maps are abundant and to the point

Diseases of the External Ear

BEN H SENTURIA, M D, associate professor of clinical otolaryngology, Washington University School of Medicine Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1957 Pp 211 63*s*

DISEASES of the skin of the external auditory meatus are hard to treat The otologist is well qualified to examine the ear canal but his training in dermatology is often insufficient to differentiate the various manifestations of skin disease there The dermatologist, on the other hand, is usually not equipped to examine and apply treatment to the external meatus Otitis externa has thus been relegated to a therapeutic no-man's-land with little basic research to aid those striving after logical treatment based on pathological and ætiological facts

Dr Senturia and the ten colleagues who helped him have done a great deal to fill the gaps by drawing on their large experience of civilian and Service patients In a well-documented monograph the many ætiological factors are discussed and the various lesions of the external canal described In a series of animal experiments otitis externa was reproduced by means of bacterial contamination combined with trauma and/or lipid removal Among the most important causes is the loss of the protective layer of waxy sebaceous secretions in times of stress, during swimming, &c The section on treatment includes advice on preventive protection of the meatal skin by wax-like ointments The book goes a long way to formulate a rational approach to this troublesome condition

Neuritis, Sensory Neuritis, Neuralgia

R WARTENBERG, M D New York and London Oxford University Press 1958 Pp 444 68*s*

BASED on his own experience and illustrated by a number of case-records, this book was completed by Dr Wartenberg shortly before his death in 1956 It emphasises the importance of mononeuritis—neuritis of a single peripheral nerve—either solitary or in association with neuritis of other peripheral nerves It does not deal, except for the sake of contrast, with polyneuritis of the Guillain-Barré and allied types The book contains a substantial bibliography (the author's assurance that he has actually consulted the items he refers to may startle some readers)

One of his main purposes is to demonstrate that a mononeuritis may result from a general systemic affection and to emphasise the clinical importance of isolated infectious mononeuritis It is stimulating to read the vigorous attack on prolapsed intervertebral disc as a cause of sciatica and to consider the rival claims of sciatic neuritis, but many will think that in this as in other directions the claims of "neuritis" are pushed too hard, especially since the diagnosis is purely clinical and unsupported by any pathological evidence

Biographical Memoirs of Fellows of the Royal Society

Vol 3 London The Royal Society 1957 Pp 328 30*s*

THIS volume contains twenty-one notable biographies, each preceded by a portrait, often of unusual excellence (one of a botanist is appropriately in colour) About a third have important medical interests Arthur Felix was one of the unique personalities of medical bacteriology, who will be remembered for his work in connection with the Weil-Felix reaction and for his discovery of the H and O antigens of organisms of the proteus and enteric groups Percival Hartley's outstanding services were concentrated on therapeutic science and biological standards Albert Jan Kluyver left a record of service to microbiology that will be hard to equal Henry Nicholas Ridley, a botanist, published papers of medical interest including one on Chinese anti-opium drugs Frederick Soddy, a chemist, was awarded a Nobel prize for his part in the conception of isotopes John William Trevan, the research director of the Wellcome Foundation, did important work in pharmacology, he once said modestly that he had had the satisfaction of starting a number of hares, most of which had finally been caught by others Hubert Maitland Turnbull had an influence in pathology far beyond the London Hospital, he had a genius for accuracy of observation and meticulous attention to detail, which he applied with fervour to everything he did Other biographies concern astronomers and mathematicians and are illustrated with rows of forbidding formulæ and equations

This splendid book should enter all scientific libraries and *all the major medical ones*

Preventive Medicine for the Doctor in his Community (*An Epidemologic Approach* 2nd ed New York and London McGraw-Hill 1958 Pp 689 77*s* 6*d*)—The first edition of this book by Prof H R Leavell, of Harvard, and Prof E Gurney Clark, of Columbia University, appeared in 1953[1] The new one is 60 pages longer, chiefly because a chapter on oral disease has been included The title has been altered from *Textbook of Preventive Medicine* and now indicates that the book is aimed at the student and practising doctor and not the specialist in preventive medicine, although there is much that the specialist can learn from it The arrangement has also been changed and the chapters are grouped into Basic Principles, Application of Principles, and Public Health—Preventive Medicine as Organised Community Action The book is unique in its field

Surgery for Pulmonary Tuberculosis

THE research committee of the British Tuberculosis Association began in 1952 to plan a comprehensive survey of the results of major surgical treatment of pulmonary tuberculosis They were joined by the Society of Thoracic Surgeons of Great Britain and Ireland and aided financially by the Medical Research Council The first report of this interesting joint enterprise has just been published.[1]

Seventy-four thoracic surgeons in the United Kingdom provided information about patients operated on during a period of twelve months in 1953 and 1954 Reference to the theatre-lists of the cooperating hospitals showed that only 12 operations were not reported—a remarkable achievement. 8236 operations were recorded This was probably 1 operation for every two or three patients with infectious sputum during the period, which indicates the magnitude of the flood of surgical treatment that followed the discovery of effective chemotherapy 6050 patients had "active" disease limited to one lung without such preoperative complications as empyema or fistula 3100 underwent some collapse operation—all but 405 a thoracoplasty—and 2950 had the whole or part of the lung removed The report deals with the two-year follow-up of these 6050 patients Such a survey requires willing cooperation from a large number of people—surgeons, physicians, and registrars If the record form is too complex, the information put on it by the clinicians may be less complete and accurate than if only a few simple facts are required Those who planned the investigation rightly chose to sacrifice detail for the sake of comprehensiveness and accuracy, and it must have been difficult to decide what detail to omit. It is unfortunate that in one respect they seem to have chosen wrongly, for details of chemotherapy were so scantily recorded that, according to the report, no use could be made of them at all The supreme importance of the correct choice of drugs and dosage and of prolonged administration was, of course, far less widely known in 1952 than it is now

Because of this serious deficiency, the recorded results of surgical treatment can be used only for internal comparisons, and even here the observed differences must be interpreted cautiously, for it is not known whether the groups on the two sides of each comparison were comparable in respect of the most important prognostic factor—drug treatment Certainly the results cannot be translated into present-day practice without reserve For instance, as many as 20% of patients without cavitated lesions had had either no chemotherapy at all or less than six weeks' chemotherapy at any stage before operation Even among the 4773 with cavities 4% had had no chemotherapy, and 45% had had infectious bronchial secretions in the three months before operation The presence of drug-resistant strains in pretreatment cultures was not recorded, no doubt because drug-sensitivity tests were not being done as a routine in all centres—nor were they being performed by the same or comparable techniques Possibly this difficulty could not have been overcome, but it seems a pity that so much valuable information about the influence of chemotherapy on surgical results had to be left out of the survey

The investigation has nevertheless yielded many valuable findings Two years after operation 85% of the whole 6050 patients were fit for work and had no signs of "active" tuberculosis A further 4% had no "active" disease, but for various reasons were unfit for work. 6% still had "active" disease, and 3% had died during the period (2% were untraced) Of the 2695 who had a thoracoplasty 2 3% died within two years 1392 had a lobectomy and 2 9% died With segmental resection the mortality was only 1 4%, but with pneumonectomy it was 10 6% These figures should not, of course, be used to compare the efficacy of the various operations, for they were done for different types of lesions and on different categories of patients For instance, 51% of those with cavities had a thoracoplasty and only 41% a resection, while the corresponding proportions among those without cavities were 20% and 76% Collapse operations were more usual in the old than the young and less common in women than men The closest approximation to a valid comparison between resection and thoracoplasty for similar types of disease can be obtained from studying the patients with cavitated lesions confined to the upper lobe There were 3514 of these In general, the more favourable cases were chosen for resection Thus, fewer had infectious sputum, healed contralateral disease, a history of five years or more, and impaired pulmonary function Despite this, the two-year results were similar following resection 89% had no "active" tuberculosis and 2 8% had died, whereas after thoracoplasty 88% had no "active" tuberculosis and 2 3% had died Further analysis showed that thoracoplasty tended to produce slightly better results in the less favourable cases In patients with both contralateral disease and recently infectious sputum there were, after two years, 3% deaths and 86% with no "active" tuberculosis among those who had undergone thoracoplasty, compared with 6% and 83% among those who had undergone resection

As expected, bronchopleural fistula proved an important complication of surgical treatment A fistula developed in 5% of patients after resection, but in a little less than 1% after collapse (and 6 of the 19 fistulas in the thoracoplasty patients followed a later resection) Infected fistula with empyema was five times commoner with cavitated lesions than with non-cavitated lesions, and arose three times more commonly in patients with infectious sputum within the three months preceding operation than in others Fistula was commoner on the right than the left side. The prognosis with infected fistulas was poor, after two years, only 41% of patients in this category were fit and free from "active" tuberculosis, and 22% had died With better drug treatment and more discriminating choice of patients for surgical treatment, the risks of this grave complication should now be considerably smaller

[1] Major Surgery for Pulmonary Tuberculosis By R S FRANCIS and M P CURWEN London Staples Press Pp 96 1955 12s 6d

One of the current problems in surgical treatment is whether to resect portions of lung containing non-cavitated tuberculous nodules in patients who have been treated by long and effective drug regimes and whose sputum, gastric contents, and laryngeal swabs are not found to contain tubercle bacilli This survey certainly shows that such patients are likely to fare well after surgical treatment There were 843 treated by resection or collapse operations who had either never had positive results of sputum examinations or not had a positive result in the six months preceding operation By the end of two years 0 7% had died, 2 3% still had "active" tuberculosis, and 95% were free from "active" disease, almost all of these being fit for work (2% were untraced) The results can be expected to be better with more efficient chemotherapy But these figures cannot be validly used to provide a reason for surgical treatment in such cases, for there are no two-year follow-up results for comparable patients treated without operation The results without surgery may be as good or better Another problem is whether to treat surgically those patients with persisting cavities but no evidence that tubercle bacilli are being excreted in the bronchial secretions while chemotherapy is continued Here also the survey gives little help There were 1354 patients with cavities who had not had a positive sputum result for more than six months before operation After two years 2 1% were dead and 4 9% still had "active" disease, 91% had no "active" disease (2% were untraced) But we do not know what chemotherapy these patients had had before and after operation, nor do we yet know what happens to patients with persisting cavities treated by efficacious drug regimes Some facts have been established by examining resected specimens of lung after treatment of different durations[2], others are being obtained by following up patients who are not operated on But it is doubtful whether it is at present possible to establish a rational treatment of both these groups of patients Certainly no dogmatic statements of policy can be anything more than expressions of belief

Carefully controlled studies of the experiences of patients of different categories randomly allocated to surgical and non-surgical groups could give valuable information Possibly in 1952, when the British Tuberculosis Association survey was planned, the time was not ripe for such an investigation Surgical treatment was popular, and long-continued chemotherapy had been little used Possibly there would have been too few physicians and surgeons with sufficient belief in the efficacy of chemotherapy to provide adequate numbers of patients Even so, it is a pity that the attempt was not made, for it seems likely that the pendulum has now swung so far the other way that such an investigation would still be unacceptable—this time because too many clinicians might be unwilling to cooperate, having seen the apparently excellent results of sustained chemotherapy without surgical treatment Operations to prevent an unknown and probably small risk of relapse in the remote future do not generally commend themselves to physicians

This, despite its imperfections, is an important survey, showing how much can be achieved by large-scale cooperation among clinicians It has been said of the survey that it is "doubtful whether in any other disease it would have been possible to present such a comprehensive picture of the results of surgical treatment the patients being treated and observed in an administrative framework almost ideally suited to large scale clinical research of this nature"[3] Chest physicians and surgeons are well placed to carry out such work through their professional organisations the British Tuberculosis Association, the Tuberculosis Society of Scotland, the Thoracic Society, and the Society of Thoracic Surgeons Several useful cooperative investigations have been made in the past few years by the British Tuberculosis Association[4] and the Tuberculosis Society of Scotland[5], and the former is collaborating with the Royal College of Obstetricians and Gynæcologists in a study of endometrial tuberculosis[6] and with the Society of Thoracic Surgeons in the survey of major surgery in pulmonary tuberculosis Next week the Association will be discussing this report at its annual conference, to be held in London

Isotopes in Absorption Studies

ISOTOPE-LABELLED fats, proteins, and vitamins are being keenly used for the study of intestinal absorption, even though some have not proved as useful as was predicted In 1949 STANLEY and THANNHAUSER[7] noted increased radioactivity in the blood after the feeding of ^{131}I-labelled olive-oil Subsequently LAVIK[8] and CHINN[9] and their co-workers developed the use of ^{131}I-labelled protein as a test of pancreatic function, pointing out that the rise in plasma values depends on the ability of the pancreas to digest labelled protein and of the normal intestine to absorb at least 90% of the digested protein The validity of the technique rests on the assumption that the iodine tag remains firmly attached during the passage of the fat or aminoacid through the intestinal cell Both TURNER and DUFFY[10,11] and REEMTSMA et al[12] with improved techniques have presented evidence that this assumption is correct

Both groups used ^{131}I-labelled oleic acid and ^{131}I-labelled triolein in developing a specific test for pancreatic insufficiency The basis of the test is that triolein (a neutral fat) requires pancreatic lipase for its hydrolysis before absorption, and ^{131}I-labelled oleic acid (a fatty acid) can be absorbed normally in the absence of pancreatic lipase In diseases of the intestinal wall, absorption curves of both substances are depressed—for example, in adult cœliac disease, intestinal lipodystrophy, and regional ileitis A normal curve after the administration of either ^{131}I-labelled triolein or protein should effectively eliminate pancreatic insufficiency as a cause of diarrhœa In obstructive jaundice evidence of pancreatic insufficiency obtained in this way is usually associated with carcinoma of the pancreas [13] Neither ^{131}I-labelled triolein nor ^{131}I-labelled albumin is of use in detecting localised neoplasm in the body of the pancreas

Such a simple interpretation of the tests cannot be applied in cases of obstructive jaundice In one of the more detailed investigations KIRSNER et al [14] noted low curves in 2 patients with carcinoma of the common duct, in whom the pancreatic enzymes were normal and the pancreas and small intestine were normal at necropsy Moreover, in cases of high-grade pyloric stenosis the results can be anomalous, and the curves might be particularly misleading in those occasional patients who have pyloric stenosis and intermittent diarrhœa KIRSNER et al [14] found excellent correlation between the curves of a ^{131}I-labelled triolein and the amounts of fat actually excreted in the stools There was in addition good correlation between the proportion of radio-isotope absorbed and the degree of steatorrhœa, except in patients with regional ileitis It might perhaps be inferred that the correlation is somewhat fortuitous since improvement in the absorptive curves in adult cœliac disease, for example, may long precede decrease of steatorrhœa KIRSNER et al noted that the absorptive curves correlated closely with the vitamin-A curves, but they concluded that it was easier to measure radioactivity in the plasma than the vitamin-A level RUFFIN et al ,[15] who have had extensive experience with ^{131}I-labelled lipids, concluded that the tests were simple and reliable, accurately reflecting fat absorption If patients who had undergone gastric operations were excluded, there were no false positive results, but the tests might be normal in patients with organic intestinal disorders In 60% of patients who had undergone operation for peptic ulcer with or without vagotomy, they noted impaired absorption of triolein Such a finding signified either impaired digestion or impaired absorption, but since the levels following oleic acid were usually normal the abnormalities must be primarily of digestion rather than of absorption Nevertheless it must be admitted that labelled fats and proteins do not give any better results than chemical methods in the detection of absorptive defects [16] The correlation of fæcal fat with plasma curves or isotope fæcal excretion is not invariably close, and, in patients in whom the defect is slight, interpretation is difficult Indeed, it would be surprising if the absorptive curves of the isotopic material were completely reliable since they are open to the errors of interpretation common to any absorptive curve

If studies with isotopic oleic acid, triolein, and amino-acids have been disappointing, because of their inability to provide clear-cut answers in doubtful cases, vitamin B$_{12}$ labelled with ^{56}Co, ^{58}Co, or ^{60}Co has led to a great increase in the knowledge of the absorption of cyanocobalamin—knowledge which can be put to practical use [17–19] Three techniques have been used—measurement of the radioactivity in the fæces,[20] measurement of the hepatic uptake,[21] and measurement of the proportion excreted in the urine [22 23] When these techniques were applied to patients with intestinal disorders it soon became evident that lack of intrinsic factor was by no means the only cause of failure of absorption of vitamin B$_{12}$, and that different parts of the intestinal tract differed in their capacity to absorb the vitamin Furthermore, there is a limit to the amount of vitamin B$_{12}$ that can be absorbed from the gut [24] The optimum dosage of labelled vitamin B$_{12}$ falls within the physiological range for absorption of this vitamin (0 5–2 µg) [22] If extremely large doses of vitamin B$_{12}$ (500 µg or more) are administered by mouth or by rectum this limiting effect may be overcome by the " mass action " effect both in pernicious anæmia [25] and in primary malabsorption syndrome [26] CASTLE [27] suggested that vitamin B$_{12}$ was absorbed mainly high in the small intestine, and CITRIN et al ,[28] who instilled labelled vitamin B$_{12}$ into the upper and lower ileum, considered that in normal circumstances this was probably true But MCINTYRE and her colleagues [29] in 2 patients with about a foot of jejunum remaining, and MOLLIN et al [30] in 3 patients with three to four feet of jejunum, were unable to demonstrate any absorption of vitamin B$_{12}$ Evidence from intestinal resection suggests that vitamin B$_{12}$ is absorbed from the ileum, and even when only two to three feet of the terminal ileum are involved, as in regional ileitis, significant impairment of absorption may be demonstrated [26 29]

Studies on patients with idiopathic steatorrhœa have shown that a high proportion do not absorb vitamin B$_{12}$[21 26 30 31] and that absorption cannot be improved by the addition of intrinsic factor or antibiotics though it is by steroid therapy **MOLLIN** et al,[30] however, called attention to patients with steatorrhœa and with gastric atrophy of the addisonian type in whom vitamin B_{12} was absorbed in addition to the intrinsic factor Whether this atrophy can be considered specific is questionable,[32] and it may well be encountered in some patients with idiopathic steatorrhœa Another condition which can interfere with the normal absorption of vitamin B_{12} is that associated with intestinal diverticulosis[33] In such patients megaloblastic anæmia is liable to develop, owing to deficiency of vitamin B_{12}, this, it has been suggested, is due to over-growth in the diverticula of intestinal bacteria which utilise the available vitamin B_{12} The anæmia often responds to aureomycin (chlortetracycline),[30] but not to neomycin[34], occasionally it responds to the addition of intrinsic factor[31] **MOLLIN** et al[30] found normal absorption of vitamin B_{12} in pancreatic steatorrhœa, while **MCINTYRE** et al[29] found in 4 patients impaired absorption, which was not improved by intrinsic factor, antibiotics, or pancreatin, but a 5th patient, who had all her pancreas removed, absorbed vitamin B_{12} normally, so it must be concluded that deficiency of pancreatin secretions could not have been the operative factor in their previous 4 patients Thus, while radioactive vitamin B_{12} has produced many conflicting observations, it has helped to reveal that vitamin B_{12} is absorbed by more than one mechanism

Annotations

ECONOMY IN PRESCRIBING

THE pharmaceutical service accounts for only some 10% of the total expenditure on the National Health Service, but its high cost has been repeatedly criticised in Parliament, partly because it is one of the few main items in the N H S on which it may seem that economy can be readily effected In 1949 the average cost of prescriptions in England was 3*s*, but by the first quarter of this year it had reached 6*s* 1½*d* The increase is due almost entirely to higher ingredient costs, the corresponding average dispensing fees for the two periods were 12 05*d* and 14 68*d* Twice economy has been sought by the imposition of a charge to patients Both times the number of prescriptions dispensed has fallen, but on the second occasion, in December, 1956, this effect was quickly offset by the increased value of individual prescriptions, which jumped to the present figure from an average of 4*s* 9*d* in 1956 In June, 1957, the Minister of Health set up a committee, under the chairmanship of Sir Harry Hinchliffe, to investigate the cost of prescriptions

In an interim report, issued last Monday,[1] this committee declares that on the whole the duty of prescribing drugs has been discharged carefully and responsibly Nevertheless, some economy is possible without loss of efficiency Comparable difficulties have emerged in other countries where health services are a charge on the community In New Zealand, for instance, between 1947 and 1957 the cost of the pharmaceutical service increased by 181%, and the prescriptions per head of population increased by 65% Drastic steps were taken, and as a general rule a practitioner may now prescribe no more than ten days' supply, and some medicaments can be prescribed only on the recommendation of a hospital authority The Hinchliffe Committee contemplated calling for similar limitation here, but decided that there were too many administrative difficulties It will, however, review this possibility again in its final report

If a general practitioner does not know the true cost of his prescribing, this may be due to either of two causes—lack of training or lack of current information As a student he may never have heard of the *National Formulary*, and the committee recommends that the alternative edition, based on a pharmacological classification, of this valuable book should be supplied to all clinical students as well as to hospital doctors In the further enlightenment of the practising doctor, the regional medical officer, says the committee, should play a more active part by providing up-to-date information on developments in pharmacology and therapeutics Doctors may be entirely unaware of the cost of the drugs they prescribe, as not all manufacturers provide such information, and some five thousand proprietary products are on the market The committee suggests that the law be amended to require manufacturers to indicate the price of their products in their literature and advertisements In addition the Ministry of Health, in conjunction with the British Medical Association and the Pharmaceutical Society, should investigate the possibility of issuing a comprehensive prescribing handbook so that practitioners may have in one volume information on medicaments and their retail price and on possible alternatives

The statistics at present provided by the Ministry are inadequate and appear too infrequently Information on the cost of a practitioner's prescribing reaches him some four months after the prescription has been issued The committee maintains that this interval could be shortened if every prescription were priced individually and the present averaging system jettisoned

The committee also proposes that the Pharmacopœia Commission should be asked to review the principles on which the selection of approved names is based, and to authorise approved names more promptly But it is well known that new preparations are introduced and become fashionable through their trade names, which are coined immediately by staff employed for the purpose, and are skilfully designed to be easily written and remembered Indeed nomenclature is often ahead of the product, and at least one firm has called in cybernetics to prepare many mellifluous names which have been patented in advance The committee accepts the view, put forward by the Executive Councils' Association, that executive councils should be directed not to supply copies of their medical and pharmaceutical lists to drug houses In practice this measure would have little effect, for these are public documents, available in post offices and libraries The thorny question of substitution, well known in the hospital world, is not touched on, but no doubt it will be considered in the committee's final report

NEOMYCIN IN OCULAR INFECTIONS

OCULAR infections continue to contribute substantially to visual disability and blindness, despite the virtual elimination of ophthalmia neonatorum and interstitial keratitis by improved methods of treatment Most infections are exogenous, and many are associated with injury, bacteriological cultures would be expected in these circumstances to indicate the appropriate antibiotic or chemotherapeutic agent, but, owing to technical difficulties, culture specimens can be obtained only from the conjunctiva and eyelids, and in the more serious corneal and intraocular infections the organism can seldom be detected in this way Accordingly the nature of the infection must still often be determined largely by clinical deduction, and the efficacy of treatment decided by therapeutic trial or prophylaxis The value of penicillin used in these ways is evident from the greatly reduced incidence of serious ocular infections (and in particular of hypopyon ulcer) since its general use became possible, but its limitations in respect of gram-negative organisms and penicillin-resistant staphylococci are reflected in the high proportion of serious infections which are now found to be caused by these organisms Sorsby and Ungar[1] found 19 such infections in a series of 61 inpatients at the Royal Eye Hospital, and they drew attention to the need for some more effective, broader-spectrum antibiotic for use both in such cases and in prophylaxis

The choice of a broad-spectrum antibiotic presents special problems in ophthalmology owing to the selective action of the blood-aqueous barrier The comparable levels in blood and aqueous for innocuous sulphonamides are 3 4 mg per 100 ml and 0 4 mg per 100 ml respectively, with penicillin penetration into the aqueous is better, and still higher levels may be achieved by subconjunctival injection of penicillin with adrenaline[2 3]

Sorsby[1] now reports trials of several broad-spectrum antibiotics in rabbits infected with penicillin-sensitive and penicillin-resistant staphylococci and with *Pseudomonas pyocyanea* and proteus Carbomycin was perforce excluded on account of poor local tolerance, and erythromycin, which also produced some local irritation, gave unpromising results when injected subconjunctivally or given by mouth The effect of subconjunctival neomycin on penicillin-resistant staphylococci infections was more hopeful (Additional oral erythromycin produced no material extra improvement) *Ps pyocyanea* and proteus alone among the gram-negative organisms give rise to suitable experimental ocular lesions, and, with the first of these, results comparable with those obtained with polymyxin B and with streptomycin were seen Intraocular infections with proteus proved impossible to control with any of the antibiotics used, but in a parallel experiment with animals pre-treated with neomycin the infection was controlled in most cases, and in a further series of experiments with gram-negative bacteria the less fulminating infections produced by intracorneal injection of proteus were controlled A final series confirmed that in infections with the common penicillin-sensitive organisms neomycin is as effective as penicillin

Thus neomycin is no less efficacious against both gram-negative and gram-positive organisms than the other individual antibiotics Moreover it has greater range, and, being suitable for subconjunctival injection, it may be the antibiotic of choice when the causal organism is unknown Early clinical experience suggests that the human eye tolerates well the repeated subconjunctival injections of neomycin necessary to maintain therapeutic concentrations, and this antibiotic is clinically effective in severe ocular infections

NEW LIGHT ON RENAL STONES

UNDERSTANDING of urinary stone will be achieved only by appreciating the conjunction of biochemistry and mechanics which must contribute to its formation[1 2] Only biochemistry will explain why calcium salts remain in urinary solution in some individuals but not in others, and on what complex matrix the stone develops, while mechanics alone can provide the answer to where in the kidney the insoluble salts first appear and how they are eliminated thence Fortunately much of the mechanical side to this problem has already been elucidated by the work of Carr,[1] who has refined his methods still further by employing microradiography in association with freeze-drying of the specimen[3] in order to substantiate his hypothesis that renal calculi are formed on calcareous particles excreted via the lymphatic system into the renal calyx. This method has great advantages over direct radiography of the fresh specimen Fresh specimens require a waterproof layer to protect the emulsion on the film or plate; moreover, they tend to dry and shrink during exposure, it is thus difficult to obtain clarity in the ultimate picture Freeze-drying not only overcomes these difficulties but also improves contrast, since the water which is thus removed has otherwise a similar coefficient for X rays to that of the tissue itself Using fine-grain film exposed when almost in contact with the kidney at operation, Carr had previously shown small opacities in the renal substance and Randall's plaques at the renal papilla, also that an apparently solitary stone often proved to be a collection of smaller stones Now, with the aid of freeze-drying and microradiography, the story has been carried a stage further, for the plaques of calcification are seen to comprise a collection of small opacities, and Randall's plaques, likewise a granular collection of calcium salts, are observed to be lying not at the renal papilla but just beside it, where the lymphatics of the renal parenchyma discharge into the calyceal fornix Calcium does not seem, therefore, to be discharged or deposited at those parts of the renal papilla where the tubules end Furthermore, Carr has revealed that the deposition of calcium particles within the renal parenchyma is often lineal and in close relation to the vessels This new evidence strengthens his belief that deposits of calcium, like small particulate matter anywhere in the body, are transported in the lymphatic system, and in this the kidney is no exception Once projected into the renal pelvis these particles form a matrix for a larger concretion

But why do calcium salts tend to precipitate out within the kidneys of some? Boyce et al[4] have studied 148 patients with recurrent stones and have found that, though their calcium intake may differ little from that of healthy controls, their urinary output of calcium is significantly higher This may be controlled in part by a diet low in calcium and vitamin D, or by phytate administration, but these measures do not cause any distinct regression of existing stones or apparently avert further stone formation In the light of Carr's work this could hardly be

expected, for, by the time one stone has become manifest clinically, so many small concretions may be present that reduction in calcium intake may not reverse the process of further stone formation As Carr suggests, the only cure may then be excision of the affected lobe of the kidney Flocks [5] has also found that hypercalcinuria is common in patients with urinary stone, and yet in 21 out of 35 cases there was no evidence of hyperparathyroidism or bone disease Increased intestinal absorption may therefore be responsible—a fact which emphasises that this problem will not be solved by urologists, radiologists, or physicians alone

AMYLOIDOSIS

WHILE the cause and method of deposition of amyloid in the tissues remain unknown, the vagaries of incidence are becoming clearer In contrast to those cases in which the amyloid disease is secondary to some known predisposing cause—such as chronic sepsis, syphilis, tuberculosis, tumours, and the more recently recognised myelomatosis, rheumatoid arthritis, and regional enteritis —there are cases of " primary amyloidosis " in which no recognised cause can be found, some of these falling into definite syndromes according to the organs mainly or primarily involved Amyloid disease affecting the central nervous system sometimes escapes diagnosis [6] Chambers et al [7] report three neurological cases in which men in the early thirties developed a form of polyneuritis or symptoms mimicking tabes In the nerves there was obvious enlargement, and biopsy revealed amyloid, which was also sometimes found post mortem under the arachnoid, in the spinal dura mater, and throughout the posterior-root ganglia Chambers et al found reports of a familial form of primary amyloidosis affecting mainly the nervous system

The heart is commonly affected in primary amyloidosis, especially in older patients, the symptoms and signs are those of progressive myocardial failure, and, when no other cause can be found, amyloid disease should certainly be suspected The amyloid may be deposited extensively under the endocardium alone or also under the pericardium, or it may infiltrate the myocardium, in some cases reported by Symmers [8] the muscle-fibres were actually transformed into amyloid substance The tongue is also sometimes involved in primary amyloidosis, causing macroglossia which may lead to difficulty in speaking, eating, and protrusion As in the heart, the amyloid may be interstitial, extending out even to the gums (biopsy of which may give the diagnosis), or it may involve the muscle-fibres themselves The skin may be involved in various ways One of the patients in the series reported by Chambers et al initially consulted a dermatologist on account of trophic lesions resulting from the polyneuritis, hæmorrhagic lesions or generalised pigmentation may develop, or there may be nodular or widespread thickening due to amyloid deposition, as in an otherwise healthy young woman with involvement of the areolæ and vulva [8] The kidneys are commonly involved in secondary amyloidosis, and in the primary form hæmaturia, the nephrotic state, or even uræmia may be the only or first sign The alimentary tract is also liable to be involved in primary amyloid disease, as also in the secondary form

There was a tendency [9] to regard primary amyloidosis as a separate entity from the secondary type Besides the different distribution and the lack of a recognised predisposing cause, the primary form seemed to be characterised by different staining reactions of the amyloid deposits, and in some cases a foreign-body reaction developed around or calcium was deposited in the amyloid In a comprehensive review Symmers [10] showed that the sites involved in primary cases may also be involved in secondary, though the incidence may be very different, all the other features can occur in either form of the disease, and accordingly all varieties are related to one fundamental disturbance He suggests that amyloid is an insoluble glycoprotein laid down in the connective-tissue ground-substance as the result of a local antigen-antibody reaction Cameron [11] admits that where it comes from and how it is produced are baffling problems Both these investigators point out that amyloid is closely related to hyaline degeneration, and in biopsy some specific stain (methyl-violet, Congo-red, iodine) must be positive before the diagnosis of amyloid disease is established

STRESS FRACTURES

STRESS fractures of leg bones are often overlooked, for not uncommonly they are detectable only with special radiographic projections In the 1939–45 war, fatigue fractures of the tibia were described by Hartley [12] in children and young adults and by Leveton [13] in Army recruits In the young patient these fractures affect the upper tibia, and often spread from a small crack across the bone to produce a complete fracture In the middle-aged and elderly, fatigue fractures tend to involve the lower end of the tibia [14] Most of these patients do not give a history of unusual muscular activity, and the fractures unite fairly rapidly

In two groups of patients stress fracture seems to be an occupational hazard Burrows [15] has described a minute infraction of the tibial cortex in male ballet dancers The lesion tends to affect the middle of the bone, and gives rise to pain, swelling, and tenderness over the crest of the tibia Many different radiographs may be necessary to reveal the crack, and in two of these patients there was sufficient doubt about the diagnosis for the lesion to be explored, the specimens removed at operation showed very little evidence of bone repair A similar lesion, slightly lower in the tibia, has been described by Devas,[16] who thinks that this explains the painful condition of the leg found in athletes in training and often known as " shin splints " These patients present with pain, usually at the start of training and subsiding with rest The pain often gets more severe as training becomes more arduous, and radiographs, which may have to be repeated several times before any abnormality is detected, will show merely a small crack running through the cortex

Stress fractures in the tibia are probably a direct result of muscle pull Treatment of these minute cracks is often difficult Immobilisation is necessary only so far as it contributes to the patient's comfort In time symptoms usually subside, but the disability from this lesion is more protracted than after a complete fracture of the bone

The Wider World

CHILD HEALTH AND DISEASE IN JAMAICA

SOME IMPRESSIONS

B D Bower

M.D Birm , M R.C.P , D C H

LECTURER IN PÆDIATRICS AND CHILD HEALTH IN THE UNIVERSITY OF BIRMINGHAM

With the large influx of West Indians into the cities of Britain in the past few years it has become obvious that the West Indies are very different from the tropical paradise of popular imagination Doctors, in particular those who have West Indians as patients, may be interested in a brief account of their socio-economic and medical background This is the outcome of six months spent at the University College of the West Indies, Jamaica, in 1957, as a visiting lecturer in pædiatrics and therefore has a pædiatric orientation

Jamaica is an island of great beauty and many problems The population is a million and a half and is increasing rapidly Most of the inhabitants are poor uneducated peasants engaged in agriculture The difficulties of this occupation are often great in an island where high mountains cover three-quarters of the land and plots are small and therefore uneconomical Industry is not yet a major factor in the island's economy, but the mining of bauxite is a hopeful start.

Most of the inhabitants are of African origin The 1943 Census gave

Predominantly African	78·1%
Other Afro-Caucasian or Afro-Asiatic mixtures	17·5%
Caucasian	1·1%
East Indian	2·1%
Chinese	1·0%

The dominance of the African ancestry is reflected in the Jamaican character Jamaicans, like Africans, are happy, volatile, unwilling to take life too seriously, and always ready to laugh loudly at its problems This carefree attitude is sometimes aggravating to Europeans but on the whole arouses admiration when it is set against the grim background of many of their lives Another admirable trait which must forcibly strike any doctor called on to examine a Jamaican patient is his or her personal cleanliness Not only in Britain but also in their own country, often under appalling conditions, Jamaicans keep themselves, their children, and their clothes clean and neat at all times

Family Life

Slavery was only abolished in Jamaica in 1838, and its legacy still has great influence on the peasant's life today To the pædiatrician a very striking difference between child life there and in Europe is seen in the concept of the family and particularly of the place of the father in the family The Jamaican peasant family is matriarchal and consists of a mother, often a grandmother, and several children, who may or may not have the same father More often than not there is no man in the household The illegitimacy-rate is 70%, the highest in the world. This in itself would not be serious if the parents had a stable union, but this is not often the case Many men have little sense of responsibility for the children they have fathered, and for various reasons maintenance orders are difficult to enforce. A child's idea of a father is therefore either a man who does not live at home but who may visit occasionally or a man who is resident but who is liable at any time to be replaced by another

Yet even a superficial study of Jamaican history prevents one from being censorious The first English settlers were young, tough, and adventurous, but tended to be "the black sheep of white families" They were not accompanied by white women and took mistresses from the imported African slaves, whom they did not, of course, marry. Marriage between slaves was forbidden because proprietary rights over slaves were exclusive to their owners, but reproduction was encouraged to swell the labour force This social pattern became firmly established over the next two hundred years

The children of slaves were cared for by more or less benevolent plantation owners, who themselves had unofficial as well as official families, and the children presented no economic problem to their mothers However, just over a century ago emancipation suddenly transferred the care of children to their mothers, who have had to bear a large share of responsibility for their upbringing since then The feckless attitude of many fathers today stems from the attitude of their forefathers Fortunately the idea of the father as a responsible head of the family is being accepted more widely, especially in the rising middle class

Malnutrition

The clinical syndromes of marasmus, kwashiorkor, and marasmic kwashiorkor are commonplace in Jamaica and form the background to many other diseases of childhood The social scene has, of course, great relevance to these disorders It is the mother who perforce feeds and rears the children and inevitably, no matter how hard she tries, she sometimes fails She often goes out to work soon after the baby's birth and, because of this early loss of the protective action of breast-feeding, kwashiorkor develops at a younger age in Jamaica than in Africa, where children may be breast-fed into the second or third year Many mothers work as "higglers" (pedlars), and their earnings are often very erratic A grandmother is a godsend, for she can look after the children by day, or they can reside with her for long periods Otherwise the mother has to pay a neighbour or a professional baby-minder out of her meagre earnings, and obviously in such a commercial contract the children will fare less well than if a grandmother is available

A boy, aged 9 months, was admitted to University College Hospital, Jamaica, with a vague history of "belly running" (diarrhœa) Except that his hair showed no depigmentation, the clinical picture was typical of kwashiorkor He was miserable and underweight (14 lb 10 oz.) and lost a further pound during treatment as his œdema cleared Dependent œdema was gross in his forearms, hands, legs, feet, and abdominal wall, and his face showed the characteristic "sugar-baby" jowls Flaky-paint dermatosis affected his limbs, areas of epidermis could be stripped by slight lateral pressure, and there were moist fissuring and depigmentation behind his ears, at the angles of his mouth, and in his perineum His liver was enlarged and firm His mucosæ were pale

Laboratory investigation showed a moderate anæmia, a low level of plasma-proteins, and abnormal liver-function tests A liver-biopsy specimen floated in water, and analysis gave a high fat-content.

Dietary and social history —He was breast-fed completely for four months His mother then went out to work as a "higgler", and for the next two months he received only morning and evening breast feeds, after which time breast-feeding was discontinued He was looked after by a neighbour during the daytime in company with his two siblings and several children of other working mothers The baby-minder was paid half a crown a week for his care, and his food was provided by his mother His father was not resident and contributed only sporadically to his upkeep His mother's weekly earnings varied between thirty shillings and nothing His diet consisted of 3 tablespoonfuls dried milk to 24 oz of water daily (i e, half-strength), some patent barley, corn-meal porridge (maize boiled in water and strained, often only the filtrate is given), and bush teas The latter are infusions of various wild plants and are widely used in Jamaica as constituents of a weaning diet, medicinally, or even for magical purposes Their possible toxicity is discussed below They have a negligible calorie and protein content

This history is fairly typical Sweetened condensed milk is also widely used, and quite often expensive proprietary milk beverages are given Poverty and ignorance are clearly the main factors which operate to produce such faulty feeding, but uninhibited advertising of these beverages in Press, shops, and on the radio is partly to blame by diverting money away from foods of higher protein value Meat and eggs are not given early in life, partly because of cost, but also because of a tradition that they are unsuitable at this period of life Hens may be kept, but the eggs are usually sold in the market

Severe anæmia often accompanies kwashiorkor and in many cases is unresponsive to the administration of oral iron and the correction of protein deficiency Folic acid by mouth produces a response in this group It is usually possible to diagnose folic-acid deficiency from a bone-marrow smear, whereas examination of peripheral blood is unhelpful (Back et al 1957) Peas in the West Indies have a high folic-acid content and, though they are a staple food for older children and adults, are considered unsuitable for infants and young children This difference in feeding habits in the two age-groups may explain why folic-acid deficiency is fairly common in the young child but unknown in the adult, who also often exists on a generally substandard diet

Treatment of kwashiorkor is easy in theory but often difficult in practice In bald summary it consists in the administration of dried skimmed milk in gradually increasing strengths until the patient can tolerate solid food, but this statement conceals a wealth of nursing ingenuity and patience, factors which are most important In spite of this, all too often a severely ill child dies for reasons which are at present ill understood Problems of kwashiorkor are under active investigation in Jamaica by Dr J C Waterlow and his team at the M R C Tropical Metabolism Research Unit

Malnutrition, a world-wide disease, is today rarely seen by the pædiatrician trained in Britain, and for this reason alone I felt my stay in Jamaica was worth while Two other conditions were equally striking, although they are of little relevance outside the West Indies

Veno-occlusive Disease of the Liver

This disease is fairly common in Jamaica and apparently very rare outside the island Its pathology, clinical features, and natural history have been described fully (Jelliffe et al 1954, Bras and Hill 1956, Stuart and Bras 1957) Its ætiology is less certain, but several suggestive observations and experiments on animals point to poisoning with bush teas (Bras et al 1957) The clinical picture is striking

A girl, aged 2½ years, was well until six days before admission to University College Hospital, when she became unwell and seemed hot The next day she vomited, and this symptom continued intermittently until admission She developed a "swell belly" and swollen feet on the day before admission She had had an average Jamaican diet, including three types of "bush teas"

On examination she was small and moderately well nourished Weight 22 lb 15 oz She had gross ascites, and her liver was enlarged (3 inches below the costal margin in the right mid clavicular line) and very firm Her spleen was impalpable A week after admission she developed a moderate right pleural effusion

Laboratory investigations—Liver-function tests were relatively normal, but liver-biopsy material showed the typical histological appearance of acute veno-occlusive disease (Bras and Hill 1956) Subintimal swelling of the small hepatic veins and atrophy of surrounding parenchymal cells were present Portal triads were normal

Progress—The pleural effusion and the ascites both resolved during the fourth hospital week, and the patient was discharged well shortly after this

It seems likely that one or more bush teas are responsible for the occlusion of the hepatic venous tree which causes the acute hepatomegaly and ascites seen in the acute stage The disease can have more serious consequences than this case-report suggests Stuart and Bras (1957) found that 19% of patients with acute veno-occlusive disease died of hepatic failure early in the disease, and only 48% eventually made a complete recovery Treatment at present is only symptomatic so that prophylaxis is of great importance

Unfortunately the weaning of Jamaicans from bush teas will be a very difficult task because they are very widely used indeed In fact, their omnipresence in the diet constitutes one difficulty in accepting them as the sole cause of the disease, which is certainly not so common as one would expect on this theory The difficulty is similar to that of accepting mercury as the sole cause of pink disease, or an excess of vitamin D as the sole cause of idiopathic hypercalcæmia Until recently many babies in Britain were exposed to these substances, but relatively few were affected However, if it is finally proved that Crotalaria, Senecio, or other plants are directly responsible for the condition as is suggested (Bras et al 1957), intensive propaganda will obviously be justified Many peasants use native plants indiscriminately, and children collect plants and concoct their own brews It will probably therefore not be practicable to suggest that only certain bush teas be avoided, and propaganda will have to be directed towards the habit itself, a formidable task

Vomiting Sickness

This is less common and less well-defined (*West Indian Medical Journal* 1953) Often occurring as an explosive illness in several members of the family at the same time, it is probably due to an ingested toxin, possibly the immature ackee fruit The ackee, like bush tea, is a very common article of diet, and the same difficulties in prophylaxis as with veno-occlusive disease will arise if it is proved that the immature ackee is responsible The patient may be admitted in coma after repeated vomiting lasting several hours, or, particularly in young children, coma and convulsions may develop without preceding vomiting The hepatic glycogen is scanty (Patrick et al 1955) and the blood-sugar level very low (Stuart et al 1955) Some patients make a dramatic response to intravenous glucose, but the disease can be rapidly fatal

Sickle-cell Anæmia

In a predominantly African population this disease might be expected to be relatively common, and in fact it requires consideration in the differential diagnosis of several symptom-complexes in childhood The sickle-cell trait is found in 5% of Jamaican children (Jelliffe et al 1954), and tests for sickling are therefore routine in hospital practice If the tests are positive, hæmoglobin electrophoresis is necessary to decide whether this finding is relevant to the symptoms and signs The usual features in the first two years of life are severe anæmia, fever, mild jaundice, splenomegaly, and the characteristic painful swellings of the interphalangeal joints of the fingers This description agrees with that of pure sickle-cell anæmia in Uganda (Trowell et al 1957) and has the same serious implications Clinical diagnosis is less difficult in Jamaica, however, because malaria is now uncommon Sickle-cell anæmia and other hæmoglobinopathies are also seen in older patients, and a local map of these disorders will soon emerge when the results of investigations in the hæmatology and biochemistry departments of the University College Hospital are available Unfortunately there is at present no proved effective treatment apart from blood-transfusion

Infectious Disease

Apart from the disorders described above, the pattern of disease is similar,to that which existed in Britain fifty years ago, with infectious diseases taking a relatively important role

Diphtheria is fairly common, and tracheotomy is often urgent, but, after the acute phase, recovery is usually uneventful

Typhoid fever is also fairly common, and clinical diagnosis can be difficult Rose spots are rarely seen, and splenomegaly and the so-called characteristic temperature chart are more the exception than the rule Moreover laboratory investigations are also unhelpful at times, for treatment with chloramphenicol may prevent a rising agglutinin titre

Tetanus is common, for few children in the peasant class wear shoes, and goats and donkeys are common and must be largely responsible for contamination of the soil and tracks where children walk and play Except in the neonatal form, therefore, infection usually occurs on the feet The results of treatment are not so satisfactory as one would wish, nor is it certain that orthodox methods give the best results In one hospital it was felt that the administration of repeated daily doses of antitoxin after the initial dose of 200,000 I U was important, and in others the patient was nursed in the main ward without sedation, for it was felt that spasms, although painful, were less dangerous than sedation Facilities for treatment by intermittent positive-pressure respiration after curarisation do not yet exist The various problems of treatment are under active consideration at present, and dogmatism on therapy is at present unjustified

Infantile gastroenteritis is as common as one might expect in a country with overcrowding and low sanitary standards and is more often due to Salmonellæ than in this country (*West Indian Medical Journal* 1954) Combined with malnutrition it can present a formidable problem, yet many patients recover surprisingly quickly without relapses, once initial dehydration has been overcome Persistent vomiting is common in gastroenteritis and in malnutrition Gastric lavage usually produces a large amount of mucus It is tempting and all too easy to blame this chronic gastritis and indeed many other infant maladies on such a dietetically abhorrent procedure as the administration of bush teas, but proof is lacking Vomiting does not appear to be a symptom of underfeeding in infancy as it is in this country It is common to find pure water lack in a dehydrated baby with gastroenteritis, and the practice, common in Britain, of giving an initial intravenous injection of physiological saline solution before starting the drip is contraindicated, since hyperelectrolytæmia is often present The amount of intravenous fluid required for maintenance is large—3 oz per lb of body-weight daily—and the risk of overhydration by an intravenous drip is much less than in this country Cross-infection in hospital, the main worry to the staff of a gastroenteritis unit in Britain, is uncommon in Jamaica This is fortunate, for in many hospitals segregation is impossible and gross overcrowding is the rule Cases of gastroenteritis, typhoid, and diphtheria are nursed alongside cases of kwashiorkor, sickle-cell anæmia, pneumonia, meningitis, tuberculosis in all its childhood forms, and other more familiar diseases The average age of the ward population is usually low (18 months or less), hence the freedom from cross-infection in gastroenteritis is not due to dilution of babies with older children Open windows and jalousies are necessary for comfort, and, I feel sure, are important in this respect as those working with infectious diseases in this country have insisted for years

Overt *syphilis* occurs frequently both in adults and children In adults cardiovascular syphilis is common, and it is quite justifiable to expect a West Indian student at his final examination to be familiar with the physical signs of aortic aneurysm, although this would not apply in Britain today Congenital syphilis is seen in most of its forms

Other Diseases

Acute rheumatism is surprisingly common, and there is a high incidence of vicious carditis (Back and De Pass 1957) Streptococcal infection and acute nephritis do not seem to be correspondingly common, and rheumatic nodules and chorea are rare One wonders whether subnutrition is in some way responsible for this emphasis on cardiac damage

In the educated middle class one meets the complaints associated with a higher standard of living, such as *enuresis*, *behaviour disorders*, and *obesity* The healthy child whose parents are convinced that he does not eat enough may well present in the outpatient clinic alongside the child with gross kwashiorkor *Behaviour disorders* in the peasant class are rarely seen at hospital, probably because they are not regarded as conditions requiring orthodox medical help Obeah men, the Jamaican equivalent of witch doctors, are still influential in the bush, and it is reliably reported that in some areas their permission is required before orthodox medical advice is sought

Some diseases, such as *vitamin deficiencies*, are surprisingly rare *Scurvy* probably has a similar incidence in Jamaica to that in Britain Simple *rickets* is almost unknown in spite of the grossly inadequate diets, which must be deficient in vitamin D In general, rickets is not rare in the tropics (Jelliffe 1955) and is usually due to traditions, such as swaddling and nursing in purdah, which lead to inadequate exposure to sunlight There are no such traditions in Jamaica The classical signs of deficiences of the vitamin-B group are uncommon, although such diseases might be expected in view of the central place of degerminated maize in the diet

Infantile pyloric stenosis is very rare, so much so that the occurrence of a case is an event in hospital practice

Neonatal Disorders

Infant mortality is high (78 per 1000 in 1951), and a large proportion of deaths is due to infection Other causes of death, operative mainly in the neonatal period, are much less important, in hospital at least, the neonatal period seems relatively safe For instance, labour is easy, during my stay I saw no baby with signs of cerebral birth injury in the obstetric department of the hospital

Prematurity, defined by birthweight, is common, but for a given weight a Jamaican premature baby is much more mature in behaviour than his European and North American counterparts Problems of temperature regulation, initiation and maintenance of respiration, and feeding are much less obtrusive than in Britain A 3-lb baby, for instance, will often take well from the breast and cause little anxiety to the nurses Relative behavioural maturity has recently been demonstrated in newborn babies in Uganda (Geber and Dean 1957)

Hæmolytic disease of the newborn is relatively uncommon, for the proportion of the population which is rhesus-negative is about half that in Britain

To the pædiatrician, then, neonatal work has less clinical interest than it has in this country

Feeding difficulties in the early months are also few Breast-feeding is widespread, on demand, and there is no false modesty about it among most mothers In such a poor country the natural method is often the only adequate method, and it is fortunate that breast-feeding is so easy for nearly all women It is sad to see the influence of advertisements for dried milk on such people The idea that breast-milk is inferior to these products is easily induced, and dried milk may be deliberately substituted for breast-milk by a mother because she understands it to be superior, although she will probably dilute it to make it last longer

Preventive Pædiatrics

It will be clear that Jamaica is no Welfare State Government medical services are mainly curative and, although the Hyacinth Lightbourne Nursing Service combines preventive and curative work in an admirable way, there is a great need for health visitors and infant-welfare clinics Diphtheria, whooping-cough, and tetanus are far too common, and there is a danger that they will continue to be accepted as inevitable because they have no news value today Poliomyelitis, by contrast, has been in the limelight recently, and in 1957 a widespread official inoculation campaign against it was undertaken in Jamaica, although in terms of mortality it has so far been no more important than the other diseases

The main problem of preventive pædiatrics in Jamaica, of course, is malnutrition The issues here are mainly economic, and its discussion is beyond the scope of this article At present UNICEF provide free skimmed dried milk to this and other countries who need it, and it is available to mothers in certain areas at a price equivalent to the cost of distribution There is a danger, however, that this very laudable arrangement will officially be taken for granted and no provisions made if the supply ceases In spite of poverty, education and encouragement can achieve much in the prevention of malnutrition It was surprising how often patients, admitted to hospital with kwashiorkor, continued to thrive after discharge from hospital although the economic circumstances were unchanged A comprehensive health-visitor service could go some of the way in preventing malnutrition

I wish to thank all those, too numerous to mention, who made my stay in Jamaica so enjoyable and educative It is to a large extent the observations and opinions of the doctors, nurses, and students of the University College Hospital and the Kingston Public Hospital which are embodied in this article Any errors must be ascribed to myself, the visitor, whose only advantage was possession of the opportunity to see diseases and situations with a fresh eye Finally, I wish to thank Prof J M Smellie, the University of Birmingham, and the British Council for making the visit possible I hope that such visits to tropical countries will become more general, for it is difficult to exaggerate their value

NOTES ON SMALLPOX VACCINATION

J C SAUNDERS
M D N U I, D P H
PROFESSOR OF HYGIENE AND SOCIAL MEDICINE,
UNIVERSITY COLLEGE, CORK

THE work on which these notes are based was undertaken, in the first instance, to demonstrate to students the technique of multiple-pressure vaccination

The Site

There are certain disadvantages in the accepted methods of administering the vaccine, the chief of which is the site favoured—the deltoid region This is an inconvenient area Except in the case of babies, coats have to be removed and shirt and other sleeves have to be rolled up and held in position over the shoulder, and these garments have to be replaced without disturbing the lymph All this has to be done again later for medical inspection and for any local treatment that may be needed

There is no valid objection to vaccination on the anterior surface of the forearm, where a Schick test is done The vaccine can be inserted much more easily with the operator sitting opposite the seated patient, and greater control can be exercised in stretching the skin and making the required pressures, and after control is also much easier An additional advantage in females is the cosmetic effect any scarring in this area is minimal and is practically never seen in ordinary circumstances

Expulsion of Lymph

It is sometimes difficult to expel the lymph from the capillary tube in which it is supplied An ingenious method of overcoming this difficulty was described by Galpine (1951) One of the broken ends of the tube is inserted into the bulbous end of an ordinary rubber teat, into the open end of the teat a glass tube, lightly plugged with sterilised cotton-wool, is inserted, and the lymph may then be expelled by gently blowing through the glass tube

This was found to work very well in practice, affording a great deal of control, but occasionally it was impossible to avoid expressing an excessive amount of lymph This difficulty was overcome by what appears to be an even simpler procedure The capillary tube is broken in the usual way with due asepsis, it is then held vertically between the thumb and the first finger, while the hypothenar aspect of the hand is tapped against a hard surface—e g , a table This brings the lymph down to the open lower end of the tube The tube is then very gently tapped against the surface of the prepared skin and, by capillarity, a small amount of the lymph comes out.

This method allows a very great deal of control of the quantity of lymph used and may prove very economical when large numbers of people have to be vaccinated Vaccinating a class of medical students I set out to ascertain how many could be vaccinated with a single tube I had got as far as vaccinating nineteen when a tiny speck of blood was observed contaminating the lymph The risk of transmitting viral hepatitis caused me to reject the remainder of the lymph, but I think there would have been no difficulty in bringing the number of vaccinations with that tube up to twenty-five.

Multiple-pressure Vaccination

In describing the multiple-pressure methods all the textbooks teach that the drop of lymph should be placed on the skin first, and the pressures of the needle made through it, but I experienced some difficulty in practising this method without drawing blood at the same time The viscosity of the lymph seems to protect the skin and thus calls for undue pressure of the needle, which therefore occasionally goes deeper into the skin than it should. To overcome this difficulty the following method was devised in which the necessary pressures are made before the lymph is applied

(1) The skin of the anterior surface of the forearm is prepared in the usual way, acetone being used for surface disinfection

(2) The operator next takes the capillary tube and breaks off each end in turn, using two sterilised pairs of forceps guarded with sterilised rubber tubing The lymph is brought to one end in the manner described above, and the tube may then be handed to an assistant or laid aside for the moment

(3) The operator then grasps the posterior aspect of the patient's forearm with his left hand and puts the skin on the stretch. Next he taps the tightened skin very gently with a no 1 straight Hagedorn needle Soon the altered appearance of the skin indicates that the necessary breach in continuity has been made the opaque silvery appearance is quite distinctive

(4) For the needle is substituted the capillary tube with the lymph shaken well down. The tube is tapped, again very gently, on the abraded surface, which is soon covered by a film of lymph whose thickness depends entirely on the number of taps At this juncture the platinum spatula of an old vaccination scarifier is used for pressing the lymph gently into the underlying cells of the cutis vera.

(5) The lymph is allowed to dry before the patient's sleeve is pulled down, and the operation may then be regarded as complete Some operators prefer to apply a dressing, in this case the only precaution needed is to make sure that an antiseptic one is not used.

It is, of course, assumed that strict asepsis is observed throughout the procedure

This method has been used in 255 adults, of whom 89 were medical students, and 244 of the vaccinated persons were followed up The after-effects differed in no appreciable way from those observed in the case of ordinary vaccination in the deltoid area The ease of examination was an outstanding advantage, as was the ease of applying either stupes or penicillin cream in the few cases of primary vaccination in which the local reaction called for treatment A further advantage was the facility with which the various stages of the lesion could be studied, this was much appreciated by the students

Vaccinia

The result of inoculating cowpox into man depends almost entirely on the patient's previous vaccination history A person who has been vaccinated more than once previously nearly always develops an immune reaction (papule formation alone without any general reaction) An adult who was vaccinated only once in infancy may develop a typical primary vaccinia or an accelerated reaction, but usually little or no general reaction or only a fleeting one In an adult who has never been vaccinated the picture is quite different, the cooperation of medical students in this inquiry has offered an opportunity of studying it closely

The conclusion that I am forced to is that vaccination should not be regarded lightly in such cases, and most certainly not the reaction which almost invariably develops after it. The peak effect, however, does not endure more than two or three days at the worst, and the patient should be warned that this will be experienced about the tenth or eleventh day, and that, no matter how bad he may feel, he will eventually recover

The notes made for me by my students indicate that there is a primary viræmia, which may occur between the fourth and seventh days, but that the brunt of the attack (corresponding no doubt to a secondary viræmia) falls between the tenth and the twelfth days Usually the reaction is severe, being ushered in by malaise, shivering, nausea, and prostration Pyrexia is an invariable accompaniment, in 1 case it was 103°F, but it is usually about 101°F At this stage lymphangitis is prominent, lasting during the pyrexia and subsiding with it, forearm vaccination afforded a very good opportunity of observing this Myalgia and headache also were prominent. In addition to the zone of hyperæmia immediately adjoining the nodal point, widespread erythema may affect the limb, in 1 case (the only one to cause apprehension) there was, in addition to the erythema, a bullous eruption involving the forearm and the upper arm Pyrexia in this case was high—100°–103°F for four days—after which the condition subsided, and recovery was uneventful Axillary adenitis was observed in practically all the cases Apart from the last-mentioned patient (who was confined to bed for a week) the longest period of rest in bed was three days

Of the 89 students the vaccination was primary in 20, of whom 16 presented the severe type of reaction In none of the remaining 69 students was the reaction such as to require treatment in bed or to interfere with their ordinary activities except, perhaps, sport for a few days

Much the same can be said of 166 other persons vaccinated Most of these came for vaccination because they were proceeding abroad In addition I saw a very much larger number who had been vaccinated by their family doctors and had to present themselves to me, as city medical officer, for authentication of their vaccination certificates

It seems inevitable that there will be a further dispersion of people to countries where smallpox is a risk or in which the health authorities require vaccination as a prerequisite for entry In view of the unpleasant reactions inseparable from primary vaccination in adults it must be regarded as a great folly to postpone this procedure in infancy

AUSTRALIAN SCHOOL OF MEDICAL RESEARCH

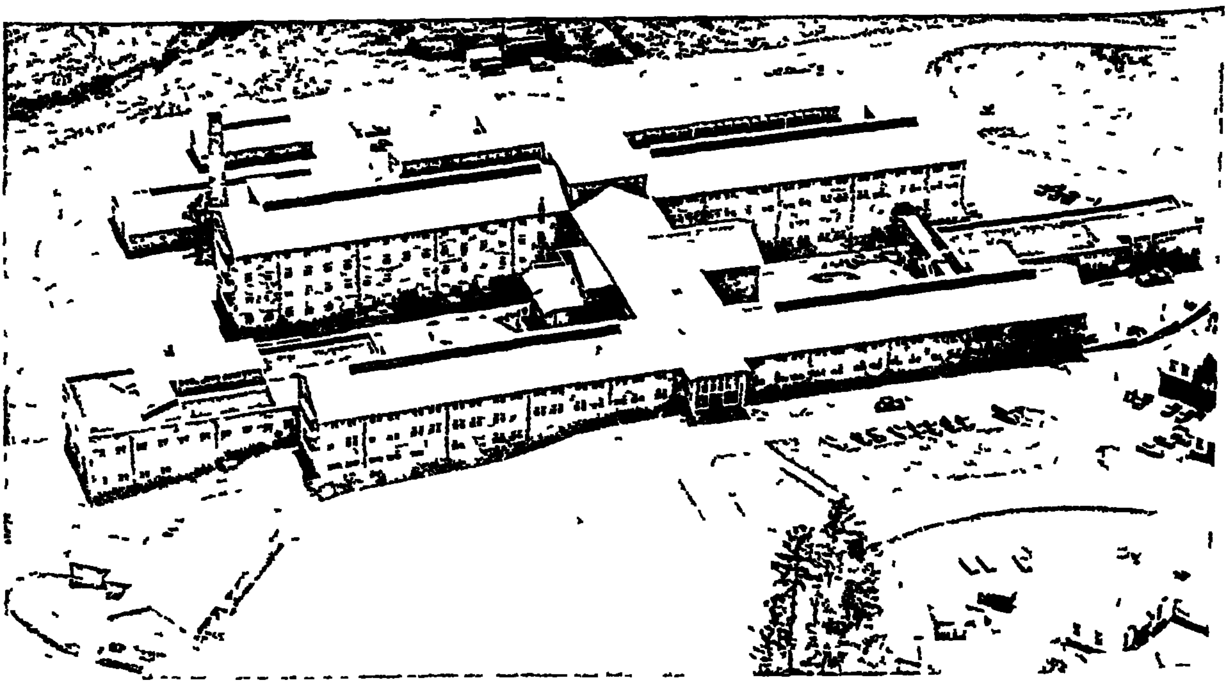
In 1946 the National University of Australia was founded as a national centre for research and research training It was Australia's constructive response to the complaints that many able scientists left the country to study and work at universities and institutions in Great Britain This depletion was most sharply felt in the medical sciences, for at that time the only Australian medical research institute with an international reputation was the comparatively small Walter and Eliza Hall Institute in Melbourne As long ago as 1944 Sir Howard Florey, himself an Australian graduate, had suggested in a report to the Commonwealth Government that a national institute for advanced medical sciences should be set up This project was accordingly included in the early plans of the new university, and until 1955 Sir Howard Florey was adviser to the council of the university in the establishment of the John Curtin School of Medical Research Last March, at Canberra, in the presence of the Australian Prime Minister, Sir Howard formally opened the buildings which are to be the school's permanent home

From its earliest days the school has thus had his support and counsel, and at its inception it followed his wise suggestion not to let men wait on bricks and mortar and in 1948 appointed professors to establish the first departments though there were then no laboratories in Canberra The departments were started in laboratory space lent by several institutions biochemistry at the Commonwealth Serum Laboratories in Melbourne, medical chemistry at the Wellcome Research Institution in London, microbiology at the Walter and Eliza Hall Institute in Melbourne, experimental pathology in Sir Howard's laboratories in Oxford, and physiology in the University of Otago in New Zealand In 1951 temporary laboratories were built in Canberra, and these were occupied between 1952 and 1957, when the departments moved to the present building

The school stands in $6^{1}/_{2}$ acres of ground within the university site, looking towards the Brindabella range It is a brick building about 170,000 square feet in floor area It is built in an H-shape, with four wings for laboratories (which are mainly on the upper two floors) and a central spine housing lecture theatre, seminar rooms, offices, tearooms, and library The lower floors house many of the service departments store, photography, media kitchens, mechanical plant, and so on There are also two animal houses, each of some 7000 square feet floor area, one for non-infected and the other for infected animals, an animal breeding establishment some four miles away, and a large light-engineering workshop

The laboratory wings have on the south side laboratories 20 ft deep and on the north side service rooms (hot rooms, cold rooms, &c) and studies 14 ft deep The laboratory layout on each floor is adapted to the needs of the particular department, but within the departments it follows a standard plan

At present there are five departments Prof A H Ennor is head of the department of biochemistry, and also dean of the school Dr F C Courtice has just been appointed to the chair of experimental pathology Prof Adrien Albert is director of the department of medical chemistry, Prof F J Fenner of the department of microbiology, and Sir John Eccles of the department of physiology At present the total research staff is about 40 and there are some 20 PH D students, but the school is still growing Several new departments will be started over the next few years to fill gaps in the present structure, and each department will be developed



In England Now

A Running Commentary by Peripatetic Correspondents

On Tuesday, at Westminster, the Royal Army Medical Corps celebrated its diamond jubilee with all the national splendour of an Abbey service After the entry of Queen Elizabeth the Queen Mother, colonel-in-chief of the Corps, a fanfare echoed exquisitely in the roof, the National Anthem was sung, and the Dean bade us join in "an act of thanksgiving, remembrance, and dedication" But amid so much that was beautiful, nothing was more appropriate than the breathtaking sight of the great nave filled with men in battledress—recalling so directly the medical services in action and the armies they have served. As the Chaplain-General said in his sermon, the R A M C has no battle honours of its own, but has a share in the battle honours of every regiment

* * *

After seeing her off on the last bus, I went to collect my cycle from the cycle-park There were still many cycles there and it took me a little time to find it. I reached out to pull it down from its rack, but there was an unfamiliar resistance—the back wheel was padlocked At first I had grave doubts as to whether the cycle was really mine I walked the length of the park looking searchingly at each cycle, then back again—no, it was mine. I gazed at the cycle forlornly and at the strange chain that bound it How had it got there? How should I get it off?—it was a stout chain and stouter lock

I gave it a smart tap with my shoe which I took off for this purpose I looked guiltily around and replaced my shoe Nobody would believe it was my cycle I tried all the keys in my pocket although I knew they would not fit Perhaps the law had put it on—the cycle wasn't really fit to be on the road If I ever freed it I vowed I would have new brake-blocks and tighten up the front wheel Feeling increasingly guilty I took a safety pin from my lapel and fiddled with the lock, hastily changing tactics and pretending to be adjusting my cycle-clips as other callous riders easily gathered their cycles and rode off

It was dark and cold I was far from home I couldn't possibly trundle it back holding up the back wheel the whole time In despair I approached the next person who showed signs of retrieving a cycle I explained my plight. It did not sound very true I felt very guilty I wondered if he would report me A night in a prison cell seemed possible He did not say anything, took the proffered pin, inserted it in the lock, and in a trice the cycle was freed. I thanked him profusely, took down my cycle feeling as if I had stolen the Crown Jewels, and rode off The strange chain was in my pocket—I would have to get rid of it at the earliest moment

I laughed to myself I wondered what the owner of the chain would think when he found his cycle safe but unshackled I let myself in through my back door and opened the cycle shed—inside was my cycle I remembered then I had of course set out by bus

* * *

My life-work is nearly at an end I have all but completed my great Contribution to scientific thought and achievement Only one thing is exercising me—*the title* I wrote the title in my mind at least 17 different ways before the first word of the thesis ever hit paper, but indecision, like choreopsis, set in and I am as far from fixing it as ever Must hurry up or someone else will publish first The obvious thing is a clear straightforward descriptive honest sort of title that tells at a glance just what it is all about, like "A Textbook of Endolymphology", except that it isn't that, or "Modern Trends in Cervical Prostheses", but it isn't that either Applying this to mine would make it something like "Some Aspects of the Dihydrophyllobothrium Reaction in Anxiety-hysteria related to Lesions of the Caudate Nucleus in Ovariectomised Albino Rats when compared with Staffelhagen's Procedure in Brazilian Long-tailed Monkeys", which no subeditor would pass unsubedited It's a good title in its way, but admittedly it lacks punch, offers no positive incentive to the reader

Rooting myself in tradition I have looked over some of my great-grandfather's books, but "On Afthma—being a Comprehenfive Difquifition upon itf Caufe, Prevention, and Cure Ufing Diverfe Phyfic, Second to None in the Britifh Empire" somehow doesn't sound quite right, even if I did change the wording to suit my rats Or I might go all Transatlantic and come out with a challenging title like "Does Phyllobothrium Make Rats Anxious?" or, even more challenging, just "RATS!" Then there's the possibility of something allegorical like "Rats through my Crystal Ball", or I could borrow something from the classics like "To Grunt and Sweat under a Weary Life", subtitled "The Experimental Rat in Times of Trouble"

On the whole I think I had really better leave rats out of it, other people don't like them as much as I do, and maybe a mention in the title might not make the impact on the general reader that it ought It must be something *attractive*, to make people sit up and get half-way through before they realise how shatteringly dull it all is Then my name will be indelibly printed on their minds as that bloke who did the unusual work on anxiety How about "A New Approach to Anxiety"? Better, but people shy off these psychiatric-sounding words I ought to stay organic perhaps a snappy combination would be the thing, like "The Relation of Lesions of the Caudate Nucleus to Anxiety", which sounds much more as if I've got to the root of something "The Caudate Nucleus and Anxiety" ? ? Oh! I don't know maybe "Rats!" was best after all

* * *

The politicians seem quite unworried about my grandchildren As Woomera, Cape Canaveral, and (until recently) somewhere in the tundra have been assaulting their genes, I have a clear responsibility to counter with firm defensive steps In my favour is the fact that their mother is now, rather proudly, 4 My least responsibility is to try to offer her children correct closure of their cardiac foramina and ductuses, and early spring seemed a convenient time to channel the german measles virus our way

The bush-telegraph duly reported Victoria on the first day of her rash My wife regarded this as a strictly clinical occasion, calling for the proper case-management of this obverse preventive medicine Other families clearly thought the responsibility lay elsewhere Victoria, surrounded by attendant mothers with an improbable number of daughters, sat nauseated but happy, accepting ever more chocolate which seemed to be the correct, the conventional, or, perhaps, merely the ritual offering There was a chorus of "Now, kiss *poor* little Vicky with her spots"

It wasn't my fault that nothing happened, nor am I in any way to blame that a chance contact a couple of weeks later produced real measles Perhaps medical training has unsuited me for causing disease

PERIPATETIC PRACTICE

I went to see my doctor
  (There were three partners more)
But I forgot that it was not
  His one weekend in four

I rang up a physician
  But found he was away
At some immense world conference,
  Somewhere in U S A

I rang up a chirurgeon
  Reply came "Not at home,
Some day this week he's due to speak
  At Brussels or in Rome"

The thought comes to my brain
  When next I have my pain
All on my own I'll telephone
  Health-Castle One, in Spain.

Letters to the Editor

THE RUSSIAN VACCINE

Sir,—The letter by Dr Liversedge in your issue of June 7 draws attention to the very troublesome situation which has developed following the publicity which has recently been given in the Press and in Parliament to the Russian vaccine

Like him we have had a large number of requests from despairing patients and their relatives for treatment with this vaccine and it has been difficult to make them understand just how speculative this treatment is and how unlikely are the chances of cure Even if disseminated (multiple) sclerosis is regarded as a virus disease it would be unique if injection of its killed virus brought about a cure once the disease was established

Two years ago, by the courtesy of Professor Sarkisov of Moscow, we received a quantity of this vaccine and since then we have used it in the treatment of 14 patients who had disseminated sclerosis (11 in the Western Infirmary and 3 in private) In all patients a full clinical history was taken and a careful assessment made of the nervous damage Before treatment was started a full explanation was given to every patient and his or her relatives of its experimental nature and our doubts of its efficacy In accord with the instructions provided, an intradermal test using 0 2 ml vaccine was done, as those showing a marked reaction should have intradermal vaccination and negative reactors should have larger dosage subcutaneously Of our patients only 4 showed marked local reactions, 2 of these were early acute cases and 2 were of several years' duration Because of the limited amount of vaccine at our disposal, and our very tenuous information as to its composition and toxicity, it was decided to treat all the patients of this first series intradermally

Of our total of 14 cases, 1 has since died of intercurrent urinary infection, and 3 are now bed-ridden 4 patients state that the treatment has had no effect on their illness and 6 claim to be improved A careful examination of these six patients shows no objective evidence of improvement of the nervous damage Of these 6 patients only 1 had a marked primary local reaction to the vaccine, and they included both early and late types of the disease In another case—a young girl with acute disease and a strongly positive skin reaction—evidence of spreading damage to the nervous system was obvious during and after treatment

We think, like Dr Lhermitte of the Saltpetriere, that these results could hardly be regarded as encouraging

The recent statement by Professor Dick that injection of the virus into animals was followed by the appearance of Negri bodies in the brain is certainly disquieting At least we can say that so far we have not encountered any definite deleterious effect

In a disease like disseminated sclerosis in which spontaneous remissions and exacerbations are the rule, and in which there is very often a large functional overlay, it is very difficult to assess the value of any form of treatment unless it is applied to a number of cases over a long time If this vaccine has curative properties we feel that out of our 14 patients we should have had at least 1 or 2 definite successes in the two-year trial period

The criticism may be advanced that our results in some cases would have been different if we had used larger doses subcutaneously We can only say that we observed no variation in results between those who had a marked local reaction to begin with and those who did not react at all

When any new form of treatment for disseminated sclerosis is suggested in the medical or lay Press it is understandable that many hopeless sufferers will immediately feel that they must try it We are familiar with many of these unfortunate essays in the past—the organic *arsenicals, protein shock, globoid bodies,* liver extracts, and latterly the copper salts To prevent sad disappointment and possible exploitation we feel that either this vaccine should be rejected as valueless and possibly dangerous or that some organised and well-controlled trial of it should be made before it is distributed Our own observations are being continued

The Western Infirmary,
Glasgow

BLUNDERBUSS WOUND OF THE ABDOMEN

Sir,—Gunshot injuries of the abdomen are still rare enough in central London to excite interest The case here reported—an injury by a blunderbuss—is probably unique during the past hundred years, and research by the firearms department of New Scotland Yard has failed to discover any parallel instance This report is made because of the unusual circumstances of the infliction of the injury rather than because it has any particular or important contribution to make to the surgery of trauma

A man, aged 58, was admitted to the Middlesex Hospital on June 30, *1949,* in emergency, with a penetrating gunshot wound of the abdomen Since he was shocked and bleeding steadily from a 1 in puncture wound at McBurney's point, he was transferred immediately to the operating-theatre where resuscitation was started No exit wound was found, and a plain radiograph showed a ball lodged on the surface of the ilium (see figure) Since rapid transfusion did not produce correspondingly rapid clinical improvement, operation was performed on the assumption that he was bleeding from mesenteric vessels Through an oblique incision, excising the wound, a large laceration of the mesentery was dealt with The terminal ileum had been breached in two places and the ball was located by the finger of Mr L Atkinson, who was assisting; the ball was embedded in the iliacus muscle immediately lateral to the right ureter, which was undamaged The ball was removed and the gut repaired No efforts were made to search for the accompanying debris, save what could easily be seen or felt Two large drains were inserted through separate incisions and the wound was closed The patient received the standard "battle" postoperative treatment of those days—i e, suction and intravenous therapy, anti-tetanus serum, anti-gas-gangrene serum, soluble sulphonamides, and penicillin There was no obvious gross infection, and he had two spontaneous bowel actions on the fifth day Two years later, in 1951, he needed repair of a small incisional hernia through one of the drainage openings Following this he was free of the symptoms of wind and distension which he had had since his injury He remains well

Shot from blunderbuss

The story of the wound is this

An eminent consulting surgeon, having attained his well-earned retirement, was moving from his house in the Harley-Street area Having no further use for an old gun which had adorned his wall he presented it to his manservant, who, delighted by this evidence of his master's regard, bore it down to his basement workshop to furbish it up. It was a brass-finished, bell-mouthed blunderbuss of percussion-cap type, and since the touch-hole did not yield to simple probing, the patient decided to burn out the occluding debris with a blow-lamp. He did this in his vice and then laid the gun down with the barrel pointing towards him and the butt pointing away from him further to clean out the bore. At this point, to his surprise, it went off. The ball was 1¹/₄ in. in diameter and was composed of multiple small segments of rusty iron, resembling chopped-up nails fused together by lead.

The former owner of the gun later made an interesting point. It had previously hung in the house of his mother in Ireland and had never, to the knowledge of anyone in the family, been used or touched. It is probable, therefore, that the loading dates back up to a hundred years, since balls of this type were not readily obtainable even in the more recent "troubles". This long lapse of time between loading and discharge is, though not unrecorded, unusual, and would seem to raise a point of what, for want of a better term, may be called preventive surgery. Despite the efforts of our export trade there may yet be a few antiques remaining in this country and some weapons among them. It would seem prudent for an owner of such heirlooms gingerly to insert a ramrod down the muzzle and to compare the internal with the external length of the barrel to the touch-hole or flash-pan. If a discrepancy exists it might be wise to seek the advice of a gunsmith. On no account should a "do-it-yourself" attempt be made to withdraw the charge.

London, N.W.1 J. H. LEES FERGUSON

HÆMORRHAGIC DIATHESIS AND OVARIAN DEFICIENCY

SIR,—The problem of hæmorrhagic diathesis in association with ovarian dysfunction, rather than deficiency, has interested me keenly for some time, and this interest was lately enhanced by Dr. Wells' article in your issue of April 26. However, before accepting the proposition that the case he describes is a hæmorrhagic diathesis due to ovarian dysfunction, or that more nebulous condition "hormonal imbalance", I think several points must be decided.

First, the "atrophic" ovary never reached the pathologist for microscopical inspection, ovaries are notoriously difficult to assess from a functional point of view at laparotomy, and section is the only way to ascertain whether or not there is any activity of the follicles. Even this can give only limited knowledge and until serum-hormone assays can be done routinely it will be extremely difficult to accept naked-eye reports of functional activity. Furthermore, one ovary may not be as good as two, but many women manage normal function on a single ovary, I do not think the absence of the patient's right ovary should lead Dr. Wells to assume any degree of hypofunction in the contralateral organ.

My second point is somewhat similar—namely, that neither anatomy, histology, nor cytology give much indication of absolute function. My own experience of these cases, from a laboratory point of view, is that although the platelets show normal morphology they are not functionally fully active, and this is borne out by the work of P. de Nicola et al. (personal communication). They showed that during the normal menstrual cycle there is a marked fall of platelet activity just before, during, and immediately after menstruation, my own findings were that in menorrhagia some women maintain this state of depressed platelet function for as long as the bleeding may last, and at times for considerably longer. All sorts of vicarious menstruation may also be met with during this period of platelet dysfunction. This can easily be assessed by serial thromboplastin-generation tests, using a standard count of one million platelets per 0·1 ml. in the test and comparing it with a similar number of control (normal) platelets. Dr. Wells does not make any mention of platelet activity, which, to me, appears to be a major omission. He also states that the patient's plasma was mixed with varying proportions of normal plasma and no coagulation defect found if, as one assumes, the patient's plasma was platelet-free or platelet-poor, this is not a surprising finding. It is a pity, therefore, that no evaluation of platelet function, per se, was attempted.

Thirdly, the difficulty of controls if women with and sometimes without menorrhagia are subjected to Hess's test, a fair proportion will be found to be positive. This is the difficult point for interpretation, Stefanini and Dameshek [1] state that œstrogen increases capillary fragility and permeability, Salvatore [2] found that the capillary fragility was increased during normal menstruation, at which time there is an alleged withdrawal of the ovarian hormones. Nevertheless, there are well-authenticated cases of purpura simplex occurring at the time of menstruation. The permeability of the capillaries, both endometrial and general, is no doubt influenced to a great extent by various hormones, and Dr. Wells has given us another example of this by showing that the capillary permeability can, in some or occasional cases, be controlled by judicious hormone therapy. This is, in my opinion, the main value of his article on this vexed but fascinating subject.

East Fremantle,
West Australia A. K. FRAZER

THE DANGEROUS WATER-STERILISER

SIR,—May I enlarge upon the noteworthy summary given by Dr. Behr (June 14) of the dangerous defects he has observed in tank forms of water/saline autoclaves in connection with outbreaks of theatre infections?

A large proportion of these tanks at present installed in the surgical theatres of this country are not in fact sterilisers but merely steam-coil boilers (disinfectors) working at less than 100°C, in addition these boilers possess no safeguard against recontamination by any one of several routes.

Three different makes of water/saline tank-form autoclaves were examined recently, apart from automatic control, they incorporated all modern developments in design including (*a*) automatic cleaning and sterilisation of the air filter and the water level gauge glass during each sterilisation run, (*b*) means to prevent recontamination of the tank contents from a leaking filler valve, and (*c*) attachments for sterilisation of the outlet faucet whenever required.

Each autoclave was designed for mains steam only and was operated by means of hand stop valves, cooling coils were fitted to the "hot" as well as to the "cold" tanks. The minimum number of stop valves to be manipulated during routine operation was 6 (12 for each pair) but, in addition, there were at least 4 further stop valves (8 per pair) to be manipulated when necessary. Though these sterilisers were of the most highly developed hand-operated designs—and costly in consequence—their operation was found to be too complicated and time-consuming for use in busy modern theatre suites. Further the continued sterility of the contents could not be assured since no stop valve remains bacteria proof and continual re-sterilisation of the outlet faucet proved impracticable, even the incorporation of automatic control would not have circumvented the latter difficulty. This confirms Dr. Behr's conclusion that "only a bottled supply of autoclaved water can be guaranteed to be sterile".

For this reason and influenced no doubt by the findings of Walter [3] and Perkins,[4] tank forms of autoclave are being replaced in both the New World and on the Continent by a system evolved for the supply of all theatre sterile fluids in bottled form. The plastic pouring lip of each glass bottle is maintained in a sterile state by means of an easily removable cap. A suitable stock of fluids is maintained in the theatre itself

THE ROLE OF VITAMIN B_{12} IN CARBOHYDRATE METABOLISM

SIR,—Since the discovery of cyanocobalamin (vitamin B_{12}) in 1948, and its crystallisation, it has been found to have not only anti-anæmic but also neurogenic and metabolic functions

We now suggest that vitamin B_{12} is concerned in carbohydrate metabolism, probably through the synthesis of glutathione, which was found in reduced amounts in the red cells in pernicious anæmia in rats deficient in vitamin B_{12} These rats were also less able to reduce glucose to ribose than normal rats [6, 7], ribose is important in carbohydrate metabolism as it enters into the adenosine phosphates (mono, di, and tri) which enter into the process of breaking down glucose to pyruvic acid through many steps Ribose also enters into the formation of coenzymes I and II, which are essential for further breakdown of pyruvic acid to CO_2 and water [8] Further evidence of the relation of vitamin B_{12} to carbohydrate metabolism lies in the fact that it abolishes the hyperglycæmia induced in rats by cortisone or large amounts of glucose [9]

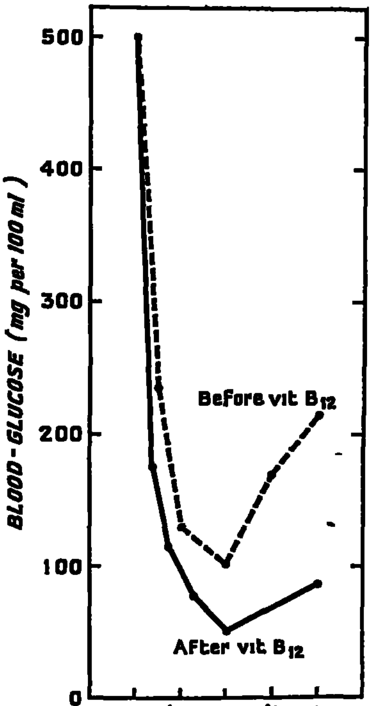

Fig 1—Insulin-sensitivity test.

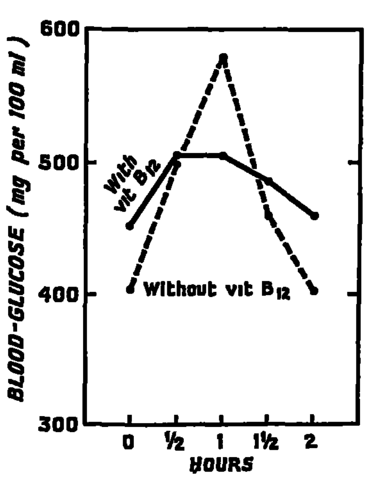

Fig 2—Intravenous glucose-tolerance curve

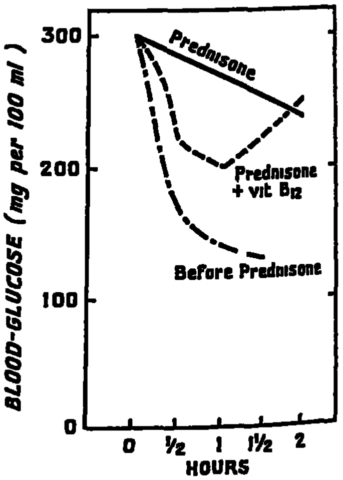

Fig 3—Insulin-sensitivity test.

In the light of this and of the current trials of vitamin B_{12} in the treatment of diabetic neuropathy, it has occurred to us to study the role of this vitamin in carbohydrate metabolism, both in normal people and in diabetic patients, where there is disturbance in this metabolism. The following experiments were carried out in 28 patients admitted to the department of medicine

Insulin sensitivity—Insulin sensitivity was tested, then 1000 µg of B_{12} was given daily for two days and the test repeated Of 20 subjects, 15 became more sensitive to insulin than before receiving B_{12} with a drop of between 30 and 150 mg of glucose per 100 ml (fig 1)

Intravenous glucose-tolerance curve—This test was done with and without the addition of 1000 µg of B_{12} intravenously, in an attempt to find out whether any possible action of it is through the liver directly The curve became flatter in 4 out of 5 cases (fig 2)

Hyperglycæmia—The effect was observed of vitamin B_{12} on the glucose-tolerance curve and insulin sensitivity in 5 diabetic patients and 3 normal people made hyperglycæmic by prednisone The glucose-tolerance curves became more normal on B_{12}, and the subjects became more sensitive to insulin—i e , the hyperglycæmia induced by prednisone was partly abolished by B_{12} (figs 3 and 4)

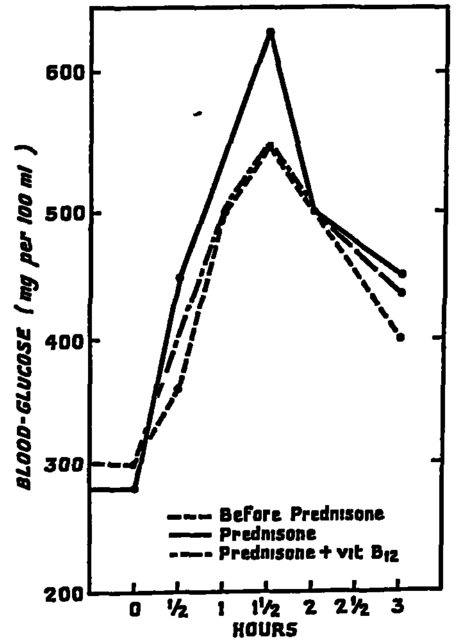

Fig 4—Glucose-tolerance curve

These results may possibly be explained through the following mechanisms

1 Vitamin B_{12} is important in the formation of adenosine triphosphate, which is essential for phosphorylation of glucose, and as insulin also probably acts on this stage through acti-

vation of the hexokinase system, B_{12} may be synergistic with insulin in this step

2 Vitamin B_{12} may favour transformation of glucose to glycogen, in a way which may or may not be similar to that of insulin, as suggested by improvement in the intravenous glucose-tolerance curves

3 Vitamin B_{12} may have an insulin-like action, because it abolishes hyperglycæmia induced in rats by administration of large amounts of glucose (which exhausts the islets of Langerhans)[9]

4 Vitamin B_{12} may antagonise some of the metabolic effects of corticosteroids on carbohydrate metabolism,[10 11] for it reduced the hyperglycæmia induced or aggravated by prednisone in man and improved both the glucose-tolerance curves and insulin-sensitivity test

SAFETY IN PROSTATECTOMY

SIR,—I was disappointed to find no reference to the late Wilson Hey in your leader of May 3

He first adopted immediate operation for all cases in 1940 and worked on the idea until his publications of 1945 and 1946 (*British Journal of Surgery* and *British Medical Journal*), in which he colourfully disposed of all catheters and preliminary drainage These papers caused immense interest, and Professor Wells was outstanding in adopting the heresy, although I notice here he mellows the message and gives these words to another "more patients die by the catheter than by prostatectomy" Wilson Hey would never have said that "every patient", he would have said, "dies by the catheter, and none by my prostatectomy"

If he had been right, and if preliminary drainage was deadly, his "immediate operation" would have been a remarkably brilliant introduction, but adopting the method without reservation at Ancoats Hospital I found that in a series of over 300 cases the retained patient beyond seventy years of age carried a heavy risk with urgent operation, overwhelmingly heavy in comparison with his coevals without retention, and his juniors with or without retention practically all the mortality was crammed into this one group

It seems to me, therefore, that McEachern's reaction to preliminary drainage is necessary only for this older patient with retention, and I would be sorry to see a complete surrender of Hey's doctrine and its attractive simplification of method

Manchester OLIVER JELLY

DEATH OF A BOXER

SIR,—In Dr Lyburn's long and distinguished career in the ring I am surprised that he cannot recall cases of cerebral injury

In hospital outpatients, as a student, I saw a case of subdural hæmorrhage in a professional boxer, and was told later that he had died Our school instructor's son neglected a medical warning to give up his professional career and became blind. Among ringside habitues Dr Lyburn must have met the odd punch-drunk, a victim of repeated minor trauma

In the amateur world damage is not likely to be as serious, a rough calculation shows that in five years at school and hospital I must personally have had between one and two hundred blows hard enough to stun momentarily without dropping, in addition to not a few heavier ones, without the production of any gross dementia now Looking back, perhaps I should have had my head examined!

There was the occasional man hazy for a while after a bout I remember two amateur light-heavies carried from the ring with concussion of longer duration than the ten second knock-out In both confusion and amnesia lasted for days Similar injuries, of course, occurred in team games, but in a smaller proportion of participants

It is the possibility of insidious blunting of the intellect which is the danger, but of which there is no present evidence (except in the punch-drunk) If there are intelligence tests delicate enough to detect any deterioration, perhaps the testing of a series of boxers at the beginning and end of their careers would produce the evidence, for or against, required by Dr Byrom

Ilford, Essex R N COMPTON SMITH

STAPHYLOCOCCAL INFECTIONS IN HOSPITAL

SIR,—In your leader of May 17 you wisely draw attention to the high incidence of staphylococcal infection and the danger of cross-infection in hospital practice

All conscientious clinicians are greatly concerned about this problem but we would wish to disassociate ourselves completely from your suggested remedy—the appointment of a hospital infection officer The British medical profession has been nationalised but there is no reason why we should follow the Civil Service procedure of creating new posts in order to share out responsibilities which are, or should be, already adequately covered Nor do we require to follow the fashion of today, medical and otherwise, of looking westwards across the Atlantic before we make our own plans

It would be pertinent to inquire who would be appointed to the post you suggest a man senior in years and of consultant status Is he to be a clinician, a bacteriologist, an epidemiologist, or a rare hybrid with unusual experience in all three? Do you suggest that this infection officer should conduct an inspection of the hands and nails of the hospital staff like a major-domo examining kitchen boys, or would you wish him to advise consultants on the proper management of their medical and nursing staffs? The consultant in charge should not need to be told what is happening in his unit, he should know for himself when and where infection exists Nurses with boils on the nose do not remain on duty because the medical staff do not appreciate the danger, but because of the gross shortage of nurses

The prevention, investigation, and control of infection in any part of a hospital is surely the direct responsibility of the clinician in charge of that section, working in cooperation with the bacteriologist, whose duty it is to keep a watchful eye on all forms of cross-infection, and constantly to exercise his detective qualities in tracing any source or possible source of danger The introduction of a third party in the person of a "hospital infection officer", can only create a barrier between clinicians and the hospital bacteriologist and prevent that close collaboration which is essential

Hospital medical staffs are fully aware of the dreadful state of affairs which permits the washing of bedpans in patients' baths, the prolonged use of contaminated curtains, inadequate washing and toilet facilities, and out-of-date theatre equipment These problems should be tackled by the administration acting on the advice of the medical staff, which should be fully represented on the hospital house committee

The efficiency and safety of hospital sterilising procedures is the day-to-day concern of the bacteriologist who should have access to wards, sterilisers, operating-rooms, toilets, laundries, &c. If this does not provide the whole answer, and if the higher flights of ecology, pathogenesis, immune relationships, and variability of staphylococci are the important matters, then surely these are also the concern of the hospital bacteriologist who is perfectly competent to deal with them

The present dangers of staphylococcal and other infections constitute a challenge which must be met by the clinicians in direct charge of their patients We most emphatically believe that the appointment of a hospital

UNUSUAL URINE PROTEIN IN MYELOMATOSIS

SIR,—Cummings[1] reported three bands in the gamma-globulin region of urine proteins in a case of myelomatosis We have observed two bands in this region in case 2 (see accompanying figure), although myelomatosis generally gives serum- and urine-protein patterns as in case 1 The smears from the sternal bone-marrow in case 2 showed numerous plasma cells and "grape cells", as described by Stich et al[2]

REVERSAL OF SUXAMETHONIUM PARALYSIS WITH NEOSTIGMINE

SIR,—In 1952 I reported[3] a case of reversal of suxamethonium-chloride paralysis with neostigmine Since then I have not had a case of prolonged apnœa until last month, when I anæsthetised two sisters, aged 9 years and 7 years, for tonsillectomy

Both children received premedication of 'Omnopon' and scopolamine appropriate for their weight, both were induced with hexobarbitone and suxamethonium bromide, and maintained on N_2O and O_2 The younger child at the end of her tonsillectomy, unlike her sister, was not breathing spontaneously

During the next half-hour she was given nalorphine, nikethamide, and methyl phenidate ('Ritalin'), with no response By this time it was established in my mind that the apnœa was due to the suxamethonium bromide solely, so I gave her gr $^1/_{100}$ of atropine followed by 2 5 mg neostigmine with almost immediate return of respirations, and no relapse

The relaxant was sent to the manufacturers who reported that it was normal in strength and quality Specimens of serum from both girls were also taken but unfortunately the person to whom they were entrusted for analysis died suddenly and they cannot be traced

Dr Bullough reports[4] a similar case in which he used edrophonium before neostigmine, which makes me think that the risk of prolonging the apnœa by the use of anticholinesterases is not so great as is generally believed, in fact, as Dr Bullough suggests, if the action of suxamethonium is prolonged neostigmine will do nothing but good

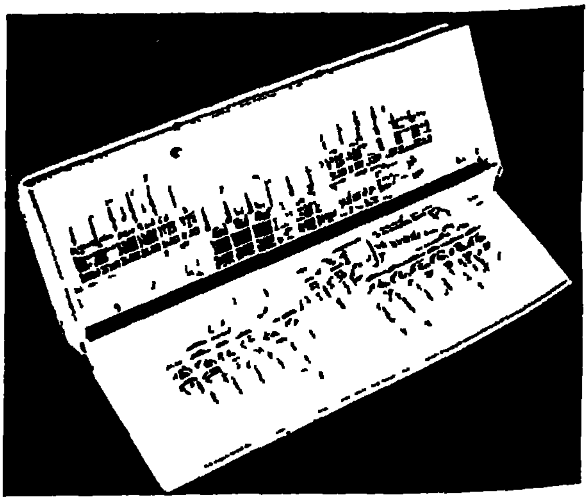
PORTABLE CONTAINER FOR AMPOULES OF VARIOUS SIZES

SIR,—The ampoule container in the accompanying illustration was designed primarily for the anæsthetist It enables him to have ampoules of various drugs immediately accessible, and has the advantage that when ampoules have been used the empty space is apparent, the drug used can be replaced, so that the necessary drugs are always available

The container, which is made of pressed steel, is about 12 in long, 4 in wide, and 4 in in depth It can be opened at either side, ensuring that the ampoules are easy to remove It holds twelve 2 ml ampoules, eighteen of 1 ml, and two each of 4 ml, 10 ml, and 20 ml—a total of 36 ampoules



Container for ampoules

The case is made by Luckham Ltd, 591/3, Kingston Road, London, S W 20 I am indebted to the photographic department of the Institute of Orthopædics, 234, Great Portland Street, for the illustration

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—You were good enough to publish an annotation (June 7) on the difficulties of understanding disc disorders I wonder if you could not have another on the difficulties of understanding Mr Charnley's hypothesis (June 14)

My first objection is to his calling it simple, and my second that it introduces a series of unnecessary postulates Doubtless (I paraphrase his words) he could state that the slow physicochemical changes of normal senescence are symptomless and the elderly person is much more prone to an attack of incomprehension than those of middle age Nevertheless may I suggest a simple scheme which does not require a biochemist or a biophysicist to reassure the practitioner, so that he can reassure the patient by explanation of his symptoms (1) discs wear out, (2) discs are liable to injury, (3) injured or degenerate discs are more liable to injury

Lumbago is a painful muscle spasm which protects a damaged disc from excessive pressure, and prevents further injury or displacement of tissue It is proportional in severity or duration to the degree of disc inefficiency

(1) Minor disc injury = mild lumbago, cured by fibrous tissue repair (2) Major disc injury or degeneration = acute lumbago, often accompanied by œdema around the disc and subjective disturbance of nerve-root function, repairing slowly, and leaving occasional nerve-root adhesions (3) Acute prolapse of degenerate disc material due to movement, or of normal material due to severe trauma, produces the fulminatingly acute syndrome of the prolapsed intervertebral disc

Need we assume that it is necessary to have a raised internal tension in the disc, due to water absorption by mucoprotein, which to fit the theory must be undegenerate, when we have the weight of the body and the force of injury as adequate substitutes? And why must the poor disc be made to go through "the physical changes of senescence in a matter of days or weeks" to explain acute lumbago? Changes in osmotic pressure may play a part in disc physiology, but need we invoke them to explain disc protrusion and lumbago? In short, if this is Mr Charnley's creed I remain apostate

London, W 1 J G BONNIN

THE TOURNIQUET

SIR,—Your leader on the tourniquet (May 31) is timely and interesting but has, I think, at least one serious omission There is no reference to the dangers of the tourniquet in the surgery of severe trauma to the limbs Where deep lacerations have produced flaps or portions of tissue of doubtful viability the use of the tourniquet may make all the difference between saving a useful portion of the limb or losing it The use of the tourniquet in such cases to make primary repair somewhat easier seems indefensible, whether the time of application is short or long

A further point concerns the debridement in this type of case One has seen surgeons attempting debridement with the tourniquet applied Under these conditions it is clearly impossible to assess the blood-supply and therefore viability of the various injured parts Also there is no visible pulsation of the arteries in or near the wound and these can easily be cut in error

The successive turns of the rubber-bandage type of tourniquet are often applied by someone other than the surgeon and can exert a tremendous compression of the limb This must add considerably to the number of painful stimuli transmitted to the brain and even under anæsthesia must aggravate shock

You state that only a pneumatic cuff should be used on the upper limb, but is it not time that a pneumatic cuff large enough for the thigh were introduced and the rubber bandage with all its dangers prohibited?

There should also be a bell, with the impact of a fire alarm, to sound when the tourniquet has been on for 45 minutes

Naturally no surgeon keeps on the tourniquet for longer than the minimum time he requires, and the operations carried out are designed to reduce the risks of infection Nevertheless it seems only logical to support Professor Pannett's contention that where the blood-supply to a limb is stopped for a time the risks of infection are increased

One condition comes to mind where the use of the tourniquet is almost indispensable—a search for a small foreign body in the hand

West Hill Hospital,
Dartford, Kent P DRANSFIELD

OVERSEAS MEDICAL SERVICE

SIR,—As a layman I write with some diffidence on a topic that has been discussed previously[1] in your journal by some distinguished medical correspondents However, I have recently enjoyed two years in the Middle East as secretary of a Government medical department The Government concerned was fortunate in having been able, over the years, to obtain the services of a number of good British doctors, who have done very fine work for the people of the country concerned and who have proved themselves to be "medical ambassadors" of the best type

Whether this high standard of medical service will continue indefinitely is another question During my two years, there were not many applicants for any of the various medical appointments advertised through the British medical press[1] This may have been partly due to the turbulent political conditions in the Middle East, but the biggest difficulty undoubtedly seems to be that, under the present National Health Service system, many good doctors are reluctant to accept posts abroad because of the great difficulties of getting back "into the swim" again should they wish to resume work in this country It seems almost equally evident that a system of secondment, as outlined in your columns by Mr Seddon and other correspondents in 1956, would do much to obviate these difficulties It would also do much to help provide the underdeveloped countries with the improved health services which they so desperately need, and at the same time provide British doctors with better opportunities for periods of service abroad —service which, to judge from some of those who have been abroad, is extremely interesting, enjoyable, and worthwhile

In writing this letter, I do not pretend to be able to add anything to the suggestions made in 1956 However, I am not aware that much progress has been made in this field since then Meanwhile, it is probably fair to say that the situation overseas with regard to this problem certainly does not seem to be improving, and there is greater need than ever for the "medical ambassadors" to whom Mr Roaf referred It seems also to be the case that there may still be "a surplus of good men in the United Kingdom" as Mr Seddon mentioned in 1956

Perhaps the matter could be considered to fall within the terms of reference of the working party recently appointed by the Government to review the problems of medical staffing and manpower

London, S W 5 M C HARDIE

SIR,—The Commonwealth is the Phœnix struggling from the ashes of the Empire May I suggest that from the ashes of our Colonial Medical Service we build a Commonwealth Medical Service directly responsible for its own administration and control to some body representing the countries of the Commonwealth Were the service well run and afforded proper status it should attract capable and experienced men and women

Such a service could be financed by all in the Commonwealth, with the wealthier countries bearing proportionately greater costs Conversely the less-advanced countries would receive most of the services, this would surely be a material and worth-while contribution by the wealthier countries to the less favoured The wealthier countries' gain would be in the greater experience and the wider and more profitable use of their doctors

---

[1] Seddon, H J , *Lancet*, 1956 i, 46 Roaf, R , *ibid* p 101 Nassau, E , *ibid* p 205 Annotation, *ibid* 1956, ii, 28

The intangible gains to all nations of the Commonwealth would be great, as such a service would bind them closer Eventually it could even attract new members, thus laying the foundation for a wider and greater Commonwealth, even though it meant finally abandoning the limiting prefix " British "

CARDIAC SYNCOPE ASSOCIATED WITH VOMITING

SIR,—We should like to describe a case of a syndrome similar to that recorded by Dr James (April 12)[1]

A housewife, aged 48, had been admitted to hospital three times and twice extensively examined in clinics because of fainting spells connected with vomiting During one of the admissions, recurrent cerebrovascular accidents were suspected

After such a fainting attack, an electrocardiogram (E C G) showed a short period of 2 1 and 3 1 atrioventricular (A-V) block, during which consciousness was normal (fig 1)

There were no history or clinical signs of heart-disease The vomiting associated with loss of consciousness hinted at the possibility of vagal stimulation as a precipitating factor

Pressure on the right eyeball (while the patient was still connected to the electrocardiograph) caused continuous A-V block (2 1, 3 1, and 4 1) (fig 1*b*) Spontaneous vomiting was followed by loss of consciousness while the tracing was isoelectric except for P waves (rate 38 per min) (fig 1*c*) After a short 2 1 A-V block, sinus rhythm reappeared with lowering of the T wave down to the isoelectric line (fig 1*d*) After several minutes, spontaneous A-V block occurred—with no clinical equivalent, because ventricular contractions were frequent enough (fig 1*f*)

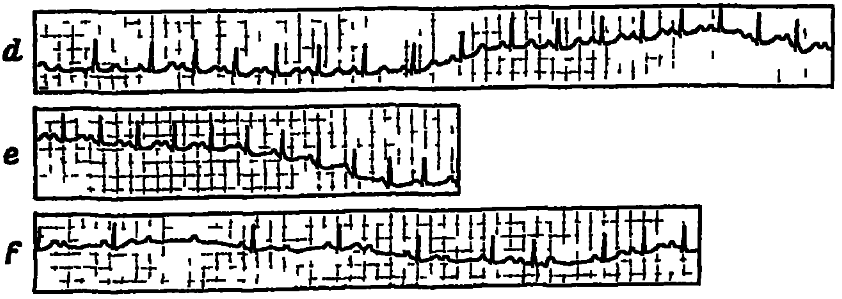

Fig 1—*a*, spontaneous A-V block with subsequent reversion to sinus rhythm, *b*, after pressure on the right eyeball; *c*, *d*, *e*, loss of consciousness with vomiting, *f*, recurrence of spontaneous A-V block

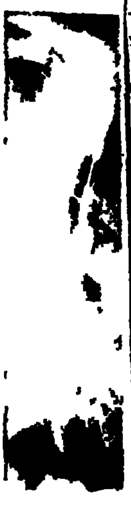

Fig 2—Barium swallow showing œsophageal diverticulum

X-ray *examination of the œsophagus* disclosed a diverticulum of its anterior wall (fig 2) The patient did not relate her attacks to swallowing or drinking, but to vomiting only Neither solid food nor pilocarpine caused attacks An attempt to introduce the metal-olive of a tube into the diverticulum caused no change in the sinus rhythm All other investigations were normal

Treatment consisted in continuous administration of atropine in small doses Three months ago the patient was discharged from the hospital She is well and is still taking atropine

Our patient has no organic heart-disease and thus differs from Dr James' patient Digitalis had not been given, as it had in Correll and Lindert's case[2] Thus, our patient comes closest to the one described by Weiss and Ferris,[1] the first recorded case of which we are aware

In our patient, a vago-vagal reflex was presumably initiated in the œsophageal diverticulum, as in all the three published cases Here, however, neither swallowing nor drinking, but only strong vagal stimulation (such as vomiting or pressure on the eyeball), could elicit the attacks

Hasharon Hospital,
Petah-Tiquah, Israel

N VARSSANO

ACQUIRED OSTEOGENESIS IMPERFECTA ?

SIR,—Osteogenesis imperfecta is generally described as a hereditary affection for which there is yet no effective treatment We have seen no description of a non-hereditary form of this disease, and the following case could be a non-hereditary condition, particularly since efficacious treatment was possible

In May, 1957, I saw a girl, then aged 2 years and 7 months, who had had many fractures due to minor trauma She had previously been examined in a university clinic The report included " blue translucence of the scleræ, skeletal X-rays revealed gracile features The compact layer was very thin Blood calcium, phosphorus and phosphatase values were normal " On the basis of these findings the condition was diagnosed as " osteopsathyrosis " It was subsequently found, however, that the parents were unaffected and that the two family histories included no suspect case of bony fragility

She was a delicate, pale child Apart from excessive flexibility of *all joints* there were a number of signs of dysproteinæmia, such as I had seen in Java during the Japanese occupation Insomnia was severe, the skin dry and withered, and development retarded (height 91 cm , weight 11 5 kg), and there were signs of hypoproteinæmia compensated by dehydration The erythrocyte-count was 5,090,000 per c mm , Hb 94% (Sicca), and a low erythrocyte-sedimentation rate (E S R) 2 mm in 1st hour, 6 mm in 2nd (Westergren) The total blood-protein value was 6 8 mg per 100 ml

Although this case may have been one of osteogenesis imperfecta it cannot be referred to as Lobstein disease, since the hereditary factor was lacking The condition was possibly acquired and symptomatic, in which case it was probably a sequel of dysproteinæmia. In the "hunger camps" of Java adults suffered from osteoporosis with spontaneous fractures as a result of protein (or general) deficiency. An explanation of the hypoproteinæmia in this case might be found in pancreatic insufficiency, since there was considerable creatorrhœa.

---

[1] Weiss, S , Ferris, E B *Arch intern Med* 1934, 54, 931

[2] Correll, H L , Lindert, M C I *Amer Heart J* 1949, 37, 446

The girl was treated with a high-protein diet and pancreatic enzyme ('Cotazym' tablets). She was also given injections of the synthetic anabolic *nor*-steroid, nor-androstenolone phenylpropionate ('Durabolin'). The initial dose was $^1/_3$ ml. (about 8 mg.) every two weeks, subsequently reduced to the same quantity once a month. After seven months her appearance had considerably improved, she was alert and active and had shed her fear of falling. The creatorrhœa had disappeared. Body-weight had increased to 15·4 kg. and height to 102 cm. The E.S.R. had risen to 4 mm. in 1st hour, and 13 mm. in 2nd, and the total blood-protein to 7·2 mg. per 100 ml. During the initial period of treatment she still had an occasional fracture under mild strain (e.g., turning while standing on a car seat). Since the seventh month after treatment began, however, she has had no further fractures in spite of increasing activity and playfulness, which involved repeated falls causing swelling and even hæmatomas. The blue discoloration of the scleræ has not changed.

Lochem, Holland. A. K. J. KOUMANS

TREATMENT OF ASTHMA AND HAYFEVER BY HYPNOSIS

SIR,—Having rejected the "intradermal, patch, scratch and prick" tests, we are grateful to Dr. Pepys (June 7) for finally putting us right about the "multiple-pressure" test, which turns out to be only the "prick test" masquerading under another name.

Clearly, publication in your journal has many advantages, not least of which is the subsequent dialectic analysis in the correspondence columns and the varied suggestions as to how future research should be conducted. Not all these, however, are very easy to understand. We learn from Dr. Moynahan (June 14), for example, that in order to find out how suggestion works, we should make controlled studies of random samples of the population. We are under the impression, on the other hand, that such studies would indicate only *if*, not *how*, such treatment works—and, of course, as now stated several times, the therapeutic effects were never under investigation anyway.

As we see it, investigations of the effects of suggestion under hypnosis can only be carried out on hypnotised subjects who respond to suggestion—and the controls should be unhypnotised subjects, or hypnotised subjects to whom no suggestions or different suggestions have been made according to the nature of the experiment. The attempted hypnosis of random samples of the population would show, as is already well known, that 20% can be put into a deep trance, 35% into a medium trance, 35% into a light trance, and that 10% will be unhypnotisable—by any single therapist. 10% of these in turn will fail to react to any attempt at hypnosis by anyone, leaving a hard core of 1% of unhypnotisable individuals in the population.

To carry out our investigations—quite apart from suitable patients, who are rare—we have a rota of about 10 deep-trance subjects, most of whom have been well conditioned to go into a deep trance on the speaking of a single code word, thus saving time otherwise wasted on induction at experimental sessions. These helpful people provide the experimental material with which we operate in our attempts to discover *how*, not if, suggestion under hypnosis produces physical changes in the human body.

In addition we should like to thank Dr. Moynahan for his really timely correction of our reference to what we thought was the von Pirquet paper on "the original allergy." If, as seems to be the case, the allergic response to old tuberculin can be inhibited by suggestion under hypnosis, whatever the mechanism, how many of the other manifestations of allergy included in von Pirquet's *allgemeiner Begriff* might respond as well? We hope to find out.

STEPHEN BLACK

RESIDENTIAL CHARGES ALLOWABLE AS INCOME-TAX EXPENSES

SIR,—Dr. Harvey-Smith's successful claim to deduct residential charges as an allowable expense for tax purposes (May 31) is the result of a directive to Inspectors of Taxes following a successful appeal to the General Commissioners of Income Tax undertaken as a test case by the Medical Protection Society.

May I therefore venture to amplify the information in Dr. Harvey-Smith's letter by pointing out that in that case the General Commissioners allowed the appeal because two essential facts were established:

(*a*) The married doctor concerned was *required by the terms of his contract* to reside at the hospital; and

(*b*) *No married quarters* were available for his use, thus obliging him to maintain a separate home for his wife at which he resided during periods of leave.

To be eligible for this concession, therefore, a resident hospital doctor for whose wife no married quarters are provided by the hospital will have to prove to the satisfaction of his Inspector of Taxes that these two conditions exist.

London, W.C.2.

ALISTAIR FRENCH
Secretary, Medical Protection Society.

ÆTIOLOGY OF PRE-ECLAMPTIC TOXÆMIA

SIR,—The crux of Professor Browne's hypothesis (June 14) is that pre-eclamptic toxæmia is caused by deoxycortone (which has not so far been shown to occur naturally), or by another undiscovered mineralocorticoid with similar properties. If any such substance were the cause of pre-eclampsia, it would be reasonable to suppose that a hint of its presence would be reflected in urinary chromatograms in eclampsia. But it is not: in fact, the excretion of formaldehydogenic substances in the urine (which are held to reflect the level of mineralocorticoids in the blood) falls as toxæmia mounts.

Again, overproduction would be expected occasionally in conditions other than pregnancy, unless placental production is alone responsible; but there is sound evidence (from a study of adrenalectomised women [1]) that the placenta contributes barely one-tenth of the corticoids present in pregnancy. The placenta cannot therefore contribute substantially to this hypothetical excess.

The occurrence of eclampsia post partum, and its recrudesence at labour when it had earlier subsided on the death of the fœtus, also indicate that the placenta plays no active role in the ætiology of pre-eclampsia.

Professor Browne holds that there may be no increase in potassium excretion in cortical overactivity; then the absence of an increased potassium excretion in toxæmia when sodium is being retained need not be set against his hypothesis. But that disregards certain data which are impossible to reconcile with his thesis, and which reinforce my view that renal ischæmia is the basis of pre-eclamptic causation—namely, the reduced glomerular filtration-rate, the glomerular ischæmia (proved by renal biopsy), and the presence of vasoexcitormotor substance (V E M) in renal-vein blood of toxæmic women (this substance never appears in the hypertension provoked by corticoids [2])

FIREPROOF CLOTHING

SIR,—Recently, as part of my training in pædiatrics, I had the opportunity to study a child, aged five years, admitted to hospital with severe clothing burns In the course of this study five shops in South London, specialising in children's clothing, were visited A total of fourteen salesladies was each asked four simple questions

Firstly, they were asked which material commonly used in children's attire was most inflammable Out of fourteen, eight had no idea, two said "flannelette and 'Winceyette'", three said "nylon", and one said "'Tricel'" The work of Colebrook et al [3] clearly shows flannelette and winceyette to be most dangerous whilst nylon and tricel are relatively safe

Secondly, each shop was asked how many customers asked questions about the fire risk of the clothes they bought At three shops the answer was "nobody", at one it was "about one a year", and at the fifth it was "two in nine years' retailing"

Seven of the salesladies knew nothing about the 1954 Fireguards Act, and seven knew of it although most had only a vague idea of its details

Somewhat surprisingly, nearly all knew of the £10 fine applicable in certain cases to parents whose children suffer burns in the home

The impression was gained that a large majority of those questioned had relatively little real interest in advising customers about the safety of the clothes purchased Perhaps this indicates a deficiency in the propaganda directed towards the group of people who retail children's clothing (and probably adult clothing as well) and who are thus best situated to advise their customers about the safety of the articles they buy

Parliament

Proposed Rebuilding of Charing Cross Hospital

ON June 17, on the adjournment, Mr MICHAEL STEWART drew attention to the proposal to rebuild Charing Cross Hospital and Medical School on the site of what is now Fulham Hospital The people of the borough, he said, did not want a teaching hospital, they wanted their own local hospital rebuilt Their objections were that a teaching hospital on that site would provide 800 instead of 950 beds, would only be able to accept some 200 instead of 700 emergency cases a year, would be unlikely to provide a special geriatric unit, would have to draw its unusual cases from a wide area and would thus have less accommodation for the people of the immediate neighbourhood

From the point of view of Charing Cross also he thought that the proposal had disadvantages The Harrow site, originally suggested for Charing Cross, had 47 acres, instead of 9 acres at Fulham, it took as long to travel by underground from Central London to Fulham as to Harrow The medical school had said that the Harrow site would not provide adequate teaching facilities, but surely the needs of the citizens of Fulham must be considered as well as the needs of the medical school

Mr RICHARD THOMPSON, parliamentary secretary to the Ministry of Health, said that it was clear that the shift of population of Greater London required some decentralisation of the hospitals which serve it This meant the development of hospital services in outer London and the reduction of the former concentration in the centre Hence it was that successive Ministers had accepted the Harrow scheme, and the Charing Cross rebuilding was selected in 1955 as a major project for early progress But because of the strong views of the University of London and the University Grants Committee that the Harrow scheme should be reconsidered in the best interests of medical education, the Minister felt bound to seek an alternative solution Many possibilities were reviewed, and last summer the site of the present Fulham Hospital seemed to provide a reasonable possibility There was an urgent local need for improved hospital facilities, and the demolition and rebuilding of the existing Fulham Hospital, which was badly damaged during the war, had already been agreed upon From the medical education angle the site of the Fulham Hospital was closer to the university than Harrow, and within easy reach of the science departments of the university It was also within the administrative boundaries of the County of London, thus conforming to the statutes of the university

The new scheme involved the rebuilding of Charing Cross Hospital and Medical School on the site of the Fulham Hospital The rebuilt Charing Cross Hospital would eventually replace the existing Fulham Hospital, Fulham Maternity Hospital and the West London Hospital The early regrouping of hospitals would take place, so that the board of governors of the regrouped Charing Cross Hospital could start work in Fulham

Discussions had taken place with the hospital authorities, all parties agreeing in principle to the proposal The South West Metropolitan Regional Hospital Board's agreement included provisos that the new hospital should provide district hospital services comparable with those proposed under the board's earlier plans for redevelopment of the Fulham Hospital and that the position of the existing staff should be safeguarded The board of governors had given assurances that a service fully adequate to the needs of the Fulham area would be provided and that it would accept the transfer of all the staff

Turning to the objections raised in Fulham, Mr Thompson said that the modern tendency was to provide a greater variety of patients for teaching purposes to familiarise students with normal cases as well as the more complicated ones which were formerly sent to teaching hospitals, and there was no reason to think that a teaching hospital could not provide a district service while fulfilling its teaching function A teaching hospital accepted patients from the Emergency Bed Service although its strict liability to do so did not go so far as that of the non-teaching hospital But in an emergency he was certain that we could rely on the hospital to help in every way possible

It was proposed that the new Charing Cross Hospital should replace Fulham Hospital with 382 beds, Fulham Maternity Hospital with 28 beds, and the West London Hospital with 238 beds, giving a total of 648 beds which ultimately would be closed The board of governors had in mind a hospital with 700 to 800 beds, with the usual range of specialties This would mean ultimately that the present total of 648 beds in the Fulham hospitals would be replaced in stages by about 750 It was proposed that 10% of the total beds should be allocated for the chronic sick which would give 70 or 80 beds That was slightly lower than Fulham's present allocation The regional board recognised the need for more beds for the chronic sick and discussions had taken place about where these might be provided

The Minister did not rule out a public inquiry, but he was not convinced that it was the best way to proceed It would entail considerable delay and expense and might not establish many facts or points of view not already known The proposals had been under consideration, and discussions had been going on since last summer, and the Minister hoped to come to a decision fairly soon

National Insurance and National Assistance Tribunals

On June 19 Mr R E Prentice moved the annulment of new regulations concerning the procedure before these tribunals The changes made by these regulations were, he said, changes of detail, but they raised points of importance One change related to legal representation before local appeal tribunals "Any person may be represented by some other person whether having professional qualifications or not " This was a fairly big departure from the existing position At the moment, in cases under the Industrial Injuries Act a claimant might be represented by a legally qualified person with the leave of the chairman, but under the National Insurance Act there was at present no provision for a lawyer to represent a claimant If it became common for lawyers to argue cases before these tribunals, the atmosphere of the tribunals might be damaged There was a tendency for a barrister to arrive with a rather wordy brief and to use legal terminology which was not often understood by his client or by some of the non-legal members of the tribunal The whole attitude of the tribunals might alter even towards claimants who were not legally represented, and we should damage the informal atmosphere People might get the impression that to succeed they needed a lawyer People who could not afford a lawyer and who lost their case might feel that if they had had one they would have succeeded

Mr Prentice also criticised another proposed change "Every hearing by a local tribunal shall be in public except so far as the chairman of the tribunal may otherwise direct if he is of the opinion that intimate personal or financial circumstances may have to be disclosed or that considerations of public security are involved " The National Insurance Advisory Committee had said that hearings should be in public unless the claimant insisted on a private hearing The regulations suggested that the chairman should decide whether or not a hearing should be in public, and the Advisory Committee thought that the claimant should have the last word Mr Prentice believed that the committee's reasoning was sound

Mr John Boyd-Carpenter, Minister of Pensions and National Insurance, referred to "the somewhat anomalous position which has existed so far" It had been the position that a claimant before a National Insurance tribunal could be represented by a friend, provided that the friend had no legal qualifications There was one case when an elderly widow who desired to be represented before a tribunal by her son was unable to do so because her son happened to be a qualified solicitor He did not believe there was any reason to assume that the right to legal representation would be very freely exercised in only the exceptional case would a lawyer appear professionally

It was not realistic, he added, to believe that the opening of the tribunals would cause immense flocks of the public to queue up to attend The Minister held very strongly that justice was much best done in public, and abuses or suspicion of abuses were much better prevented if judicial bodies did their duty in public where the Press could report what was done, and where if anything was done amiss, newspapers, the public, and members of parliament could take the necessary steps There were circumstances in which someone might genuinely be deterred from going to the tribunal if he felt that intimate and personal matters might be brought out in public, and that was a problem which to some extent faced those who attended courts of law, where closed sittings were very exceptional

At the end of the debate Mr Prentice withdrew his motion

Atmospheric Pollution on Thames-side

In an adjournment debate, Mr Bernard Braine spoke of the continued pollution of the atmosphere by emanations from the Thames-side oil refineries Up to a few years ago South-East Essex had a reputation of having almost the purest air in the United Kingdom Now, although the nuisance was intermittent, it was never far away

Mr J R Bevins, parliamentary secretary to the Ministry of Housing and Local Government, replied "quite categorically" that there was no evidence at all at present that these smells were in any sense injurious to health Nevertheless, he sympathised with those who were assailed by these odours "Our aim, which is, I believe the aim of the oil companies as well—I emphasise that—is to see that everything possible is done to remove the sources of these complaints in two ways first of all, by the more rigorous supervision of the plants and, secondly, by a readiness to deal quickly with any source of smell which may be detected by the local residents"

QUESTION TIME

Cost of Prescriptions

Mr Arthur Blenkinsop asked the Minister of Health what was the average cost per prescription prescribed under the National Health Service as at the latest available date, and the answer was approximately 6*s* 4¾*d* in April, 1958 Was the Minister aware, Mr Blenkinsop continued, that the last figure given, at the end of last year, was 4*d* per prescription less? Was he satisfied that the arrangements made with the drug manufacturers were working properly?—Mr Derek Walker-Smith replied that he thought they were, but he would continue to keep the matter under review He was already giving active consideration to the interim report of the Hinchliffe Committee, and he was in consultation about it

In answer to a supplementary question, Mr Walker-Smith said that an examination of samples in the last year showed that expensive corticosteroid preparations which became available in that year and in 1956 were being increasingly prescribed It was likely that this trend towards expensive preparations had continued

Distribution and Recruitment of Nurses

Mr J Johnson asked the Minister what steps he was taking to ensure that there was an equitable distribution of nurses as between the London teaching hospitals and the smaller provincial hospitals Mr Walker-Smith replied that the problem of distribution generally was before the National Consultative Council on the Recruitment of Nurses and Midwives, and he would consider it in the light of the advice they gave Was it not true, Mr Johnson added, that there were large queues and waiting-lists of young nurses for London hospitals? Would it not be possible to devise a voluntary scheme whereby eclamptic causation—namely, the reduced glomerular filtration-rate, the glomerular ischæmia (proved by renal biopsy), and the presence of vasoexcitormotor substance (V E M) in renal-vein blood of toxæmic women (this substance never appears in the hypertension provoked by corticoids[2])

Turning to the objections raised in Fulham, Mr Thompson said that the modern tendency was to provide a greater variety of patients for teaching purposes to familiarise students with normal cases as well as the more complicated ones which were formerly sent to teaching hospitals, and there was no reason to think that a teaching hospital could not provide a district service while evident in the cause of charity—for example, to assist the dependants of one who had been unfortunate Himself ndefatigable, he insisted that everybody else should be equally ntiring Loyalty was the keynote of his character loyalty to his school, his university, his hospitals, his Lodge, and, whilst a good hater, friendship was to him a sacred trust He fearlessly expressed his opinion in the interests of truth and justice regardless of personal consequences, through antagonising those who might adversely influence his career

I recall an episode fully thirty-five years ago when we were the two juniors on the staff of a famous special hospital The staff had been summoned to be addressed by an arrogant self-opinionated chairman of the hospital who had a proposition of a revolutionary character that threatened to undermine professional liberty At the conclusion he said, " And now I'll leave you gentlemen to talk it over I don't wish to convince you against your will " Dead silence ensued, not a word from the seniors, men of eminence Dead silence and then Arnold Stott in a quiet clear voice, " If you won't mind my saying so, I don't think you're particularly anxious to convince anybody about anything " Courteous—but devastating!

Never robust, Arnold suffered frequently from attacks of bronchial infection His last few years were clouded by almost complete disablement endured with great courage and a determination that repeatedly confounded dogmatic prognosis

He married in 1911 Lily, daughter of Alfred Robert Holland There were a son and two daughters of the marriage

JOHN LAMBERT

O B E, M.A, M D Cantab, D.P H

Dr John Lambert, who, as medical officer to Wellington College for over a quarter of a century, became well known for his work in school medicine, died at Crowthorne, Berkshire, on June 16, at the age of 78

He was brought up in Cambridge, and from the Perse School he went on to the university In 1901 he obtained first-class honours in the natural sciences tripos before going to the London Hospital, from which he qualified M.B in 1904. He held a clinical assistantship at the Hospital for Sick Children, Great Ormond Street, and later joined the Brighton Education Committee, to which he became senior school medical officer From Brighton he went to Lancing College as resident medical officer In 1909 he graduated M D During the 1914–18 war he served as a surgeon lieutenant in the Royal Navy, and for his services he was appointed O B E From 1919 until 1946 he was medical officer to Wellington College, Berkshire, and to preparatory schools in the neighbourhood, at first combining the duties of medical officer and of housemaster of a waiting house

Dr Lambert is survived by his second wife, formerly Miss Vera Pledger

A colleague writes

When John Lambert applied for the post at Wellington College, he impressed Dr W W Vaughan, then headmaster of Wellington and later of Rugby, who stands out as a judge of character, for about a score of men of his choice became headmasters of famous public schools Lambert justified Vaughan's selection He was noted at Wellington for accurate diagnosis, friendliness, sound advice, and imperturbability in a crisis Soon after his arrival, he introduced an X-ray apparatus for routine use in the sanatorium, but generally he was not keen on introducing every new method

Lambert wrote little but was proud that his predecessor, H G Armstrong, had been the first to describe the descent of the testicle at puberty His own article on torsion of the testicle showed what detailed notes he kept of his patients, and his successor found his medical records of great help

He was the most ardent attender of meetings of the Medical Officers of Schools Association, and both in council and at the general meetings spoke from his own experience and often brought an air of sanity to a discussion. He was hon secretary from 1925 until 1936 and thereafter president until 1938 He was editor of the *Annual Proceedings* until 1947 Even after his retirement from Wellington he continued to attend very regularly

In his early days he played cricket and golf, and he was always a most enthusiastic and successful gardener

HENRY MANNING PEREIRA

L R C P E, D P H

Dr Pereira, who died on June 11 at the age of 87, was one of that famous medical team who worked under T F Ricketts in the Hospital Ships and River Ambulance Service during the smallpox epidemic of 1900–02 Thereafter he never ceased to practise, and to preach, that great master's teaching on the diagnosis and the hospital management of smallpox

Because of his characteristic modesty, to the medical world at large Pereira was probably the least well-known member of that team, but those of us who worked under him learned more about smallpox from him than from any other source, and his value, especially to medical officers of health, as a consultant—a real smallpox expert of the Ricketts school—was, of course, outstanding and almost unique

In addition to his smallpox experience Pereira possessed an exceptional knowledge of diphtheria, enteric fever, and the old type of scarlet fever, gained from years of work in the fever hospitals of the Metropolitan Asylums Board, and when the London County Council took over those hospitals in 1930 he was appointed medical superintendent of the Eastern Hospital at Homerton, where he remained until his retirement

Pereira was a most lovable man, supremely happy in his family life There are many of us who will treasure the memory of his friendship

J P M

PETER PAUL DEBONO

O B E, M D Malta, F R C S, D.P H

Prof P P Debono, who died on June 3 at the age of 67, held the chair of surgery in Malta for twenty-five years, during which by practice and teaching, often in difficult circumstances, he did much to enhance the standard of surgery in the island

After graduating in 1910, Professor Debono worked for a year in London Returning to Malta he first took a teaching appointment in pathology and anatomy, and in the 1914–18 war he was associated as pathologist with the Royal Naval Medical Service and the R.A M C After the war he turned to surgery, and in 1919–22 he did postgraduate work in England, first at St Bartholomew's Hospital, London, and latterly in Manchester, obtaining the F R C S in 1920 In 1926 he was appointed professor of surgery and senior surgeon of the Central Hospital, Malta In 1944 he became chief surgeon of the Emergency Medical Services of Malta He retired from the chair in 1951 but continued to practise until his death In 1936–39 he had served as a nominated member of the Executive Council of Malta, and in 1947 he was elected a member of the Legislative Assembly, of which he was subsequently appointed Speaker, and served as Minister of Health

Professor Debono married Miss L Briffa in 1918, and there were two daughters of the marriage

J H S writes

I first met P P Debono early in1943 He was still professor of surgery in Malta and working under conditions such as can never have been experienced by any senior clinical teacher before or since His " hospital " was in a requisitioned building in Hamrun a few miles outside Valletta, and it was an unsuitable place for the care of patients and particularly for those requiring surgical treatment There were other difficulties too The shortage of food and, still more, the lack of soap were the cause of skin infections that became epidemic. In the place where I

London teaching hospitals were linked with hospitals like those at Rugby, Nuneaton, and Leicester, so that nurses, perhaps at the beginning or the end of their four years, could spend one year in our provincial hospitals which at the moment were lacking nurses? Teaching hospitals had already been encouraged, said Mr **Walker-Smith**, to send their student nurses for periods of training to sanatoria and mental hospitals in particular A compulsory arrangement of the kind suggested would be prejudicial to recruiting

Mr **E Johnson** asked the Minister if he was aware that there was a shortage of nurses in general hospitals, what had been the trend of recruiting during the past five years?—Mr **Walker-Smith** While there are shortages in some hospitals, there has been a most satisfactory increase in the total numbers of nursing staff during the past five years

The numbers of whole-time and part-time nursing staff of various grades in hospitals, other than mental and mental-deficiency hospitals, at Dec 31, 1952 and at Sept 30, 1957, were as follows

	At Dec 31, 1952	*At Sept 30, 1957*	*Increase or Decrease*
Trained nurses			
Whole-time	32,334	36,215	+3881
Part-time	6498	10,238	+3740
Student nurses	44,932	47,128	+2196
Other nursing staff			
Whole-time	29,183	26,891	−2292
Part time	10,678	16,591	+5913
Total			
Whole-time	106,449	110,234	+3785
Part-time	17,176	26,829	+9653

During this period the number of whole-time trained nurses at all hospitals, other than mental and mental-deficiency hospitals, increased by 12% and the number of student nurses by nearly 5% All classes of whole-time nursing staff together increased by 3 6% and of part-time nursing staff by 56 2%

Doctors for Colonial Territories

Mr **Arthur Blenkinsop** asked the Secretary of State for the Colonies whether he was aware of the shortage of doctors in the Colonial Service, and what steps he was taking to encourage young doctors from Great Britain to take appointments in the West Indies and other Colonial territories —Mr **J D Profumo** replied I am well aware of the constant demand for doctors in the medical departments of the overseas territories, which the Minister is doing his best to meet Vacancies in the West Indies and other territories are advertised in the professional journals as they are notified In addition, special arrangements have been made to allow applications from young doctors to enter the Colonial Service as an alternative to National Service —Mr **Blenkinsop** Will the Minister consider having some consultations with the teaching hospitals to see whether any kind of guarantee can be given to young men entering for temporary service that their chances of promotion in this country are not thereby spoiled?—Mr **Profumo** That is something I should like to look at

Mrs **Lena Jeger** Can the Minister bring this problem more closely before the Minister of Health, who, not long ago, received a report from a committee which suggested that there should be a limitation on the intake of medical students because of the danger of the profession becoming overcrowded?

Malnutrition in East Africa

Mrs **Joyce Butler** asked the Minister if he would consider setting up a nutrition department under the auspices of the East African High Commissioner for the purposes of food and food consumption research, diet improvement, and propaganda, and to coordinate the various activities undertaken to counteract malnutrition among children and adults in Uganda, Tanganyika, Kenya, and Zanzibar —Mr **Profumo** replied Coordination of such activities is already the function of the East African Council for Medical Research, under the auspices of the East Africa High Commission services, the East African Institute for Medical Research, and the East African Statistical Department A big contribution is also being made by the Infantile Malnutrition Research Unit run by the United Kingdom Medical Research Council in Uganda with the cooperation of the local and High Commission authorities

Obituary

ARNOLD STOTT

K B E, M A, B Chir Cantab, F R C P

Sir Arnold Stott, who died at his home in Surrey on June 15, at the age of 72, was consulting physician to the Westminster Hospital, on whose active staff he had served for over thirty years, during which he made a name as cardiologist and general physician

Arnold Walmsley Stott was born at Oldham in 1885, and received his early education at Rugby School From there he went up to Cambridge, where in 1907 he took the natural sciences tripos before going on to St Bartholomew's Hospital, qualifying M R C S in 1909 Three years later he gained the M R C P, but it was not until 1917 that he returned to Cambridge to graduate B CHIR

After qualifying he held a series of appointments at Bart's and the Royal Chest Hospital, and his association with the latter hospital was maintained throughout his working life In the 1914–18 war he served in France with the rank of major After demobilisation he returned to London, and in 1919 he joined the honorary staff of the Westminster Hospital In 1927 he was elected F R C P During the 1939–45 war he served, with the rank of major-general, as consulting physician first to the B E F and latterly to Northern Command He was created K B E in 1946 He retired from the active staff of the Westminster in 1950 At various times he examined for the University of Cambridge, the University of Birmingham, and the Royal College of Physicians of London

As a colleague and friend, A A writes

To some people, Sir Arnold Stott typified the flaneur And yet even the least discriminating, inclined to superficial judgment, must have felt puzzled to reconcile this character with a man appointed to the Royal Household, selected as consulting physician to the B E F on the outbreak of the world war, whose services were appreciated by promotion to major-general and the award of a K B E The fact was that a façade of apathy and apparent indifference concealed exceptional ability

He passed all his examinations with ease whilst displaying no interest in prizes or academic distinctions So far from taking an M D, he did not present the comparatively trivial thesis which at that time was a requirement for the Cambridge M B He was satisfied with the qualification essential for a staff appointment Although particularly identified with cardiology, he was a general physician in the best sense of the term The product of a worthy apprenticeship in the pathological department at St Bartholomew's, without aspiring to brilliant diagnoses in obscure conditions, with shrewd judgment and stability in fundamentals, his opinion was always of value For, apart from his training, he had an exceptional clinical instinct He seldom participated at medical meetings and wrote but little Yet these rare occasions exhibited in no small degree a gift of expression through the tongue and by the pen that others envied whilst deploring his reluctance to apply himself in proportion to his ability Indeed ability was evident in all his undertakings whether administration in a medical school, the organisation of an Army's medical services, or the management of a dining club

He had a remarkable capacity to stimulate and to interest without any appearance of effort More than once this was evident in the cause of charity—for example, to assist the dependants of one who had been unfortunate Himself indefatigable, he insisted that everybody else should be equally untiring Loyalty was the keynote of his character loyalty to his school, his university, his hospitals, his Lodge, and, whilst a good hater, friendship was to him a sacred trust. He fearlessly expressed his opinion in the interests of truth and justice regardless of personal consequences, through antagonising those who might adversely influence his career

I recall an episode fully thirty-five years ago when we were the two juniors on the staff of a famous special hospital The staff had been summoned to be addressed by an arrogant self-opinionated chairman of the hospital who had a proposition of a revolutionary character that threatened to undermine professional liberty At the conclusion he said, " And now I'll leave you gentlemen to talk it over I don't wish to convince you against your will " Dead silence ensued, not a word from the seniors, men of eminence Dead silence and then Arnold Stott in a quiet clear voice, " If you won't mind my saying so, I don't think you're particularly anxious to convince anybody about anything " Courteous—but devastating!

Never robust, Arnold suffered frequently from attacks of bronchial infection. His last few years were clouded by almost complete disablement endured with great courage and a determination that repeatedly confounded dogmatic prognosis

He married in 1911 Lily, daughter of Alfred Robert Holland. There were a son and two daughters of the marriage

JOHN LAMBERT

O B E, M A, M D Cantab, D.P H

Dr John Lambert, who, as medical officer to Wellington College for over a quarter of a century, became well known for his work in school medicine, died at Crowthorne, Berkshire, on June 16, at the age of 78

He was brought up in Cambridge, and from the Perse School he went on to the university In 1901 he obtained first-class honours in the natural sciences tripos before going to the London Hospital, from which he qualified M.B in 1904 He held a clinical assistantship at the Hospital for Sick Children, Great Ormond Street, and later joined the Brighton Education Committee, to which he became senior school medical officer From Brighton he went to Lancing College as resident medical officer In 1909 he graduated M D During the 1914–18 war he served as a surgeon lieutenant in the Royal Navy, and for his services he was appointed O B E From 1919 until 1946 he was medical officer to Wellington College, Berkshire, and to preparatory schools in the neighbourhood, at first combining the duties of medical officer and of housemaster of a waiting house

Dr Lambert is survived by his second wife, formerly Miss Vera Pledger

A colleague writes

When John Lambert applied for the post at Wellington College, he impressed Dr W W Vaughan, then headmaster of Wellington and later of Rugby, who stands out as a judge of character, for about a score of men of his choice became headmasters of famous public schools Lambert justified Vaughan's selection. He was noted at Wellington for accurate diagnosis, friendliness, sound advice, and imperturbability in a crisis Soon after his arrival, he introduced an X-ray apparatus for routine use in the sanatorium, but generally he was not keen on introducing every new method.

Lambert wrote little but was proud that his predecessor, H G Armstrong, had been the first to describe the descent of the testicle at puberty His own article on torsion of the testicle showed what detailed notes he kept of his patients, and his successor found his medical records of great help

He was the most ardent attender of meetings of the Medical Officers of Schools Association, and both in council and at the general meetings spoke from his own experience and often brought an air of sanity to a discussion. He was hon secretary from 1925 until 1936 and thereafter president until 1938 He was editor of the *Annual Proceedings* until 1947 Even after his retirement from Wellington he continued to attend very regularly

In his early days he played cricket and golf, and he was always a most enthusiastic and successful gardener

HENRY MANNING PEREIRA

L.R.C.P E, D P H

Dr Pereira, who died on June 11 at the age of 87, was one of that famous medical team who worked under T F Ricketts in the Hospital Ships and River Ambulance Service during the smallpox epidemic of 1900–02 Thereafter he never ceased to practise, and to preach, that great master's teaching on the diagnosis and the hospital management of smallpox

Because of his characteristic modesty, to the medical world at large Pereira was probably the least well-known member of that team, but those of us who worked under him learned more about smallpox from him than from any other source, and his value, especially to medical officers of health, as a consultant—a real smallpox expert of the Ricketts school—was, of course, outstanding and almost unique

In addition to his smallpox experience Pereira possessed an exceptional knowledge of diphtheria, enteric fever, and the old type of scarlet fever, gained from years of work in the fever hospitals of the Metropolitan Asylums Board, and when the London County Council took over those hospitals in 1930 he was appointed medical superintendent of the Eastern Hospital at Homerton, where he remained until his retirement

Pereira was a most lovable man, supremely happy in his family life There are many of us who will treasure the memory of his friendship

J P M

PETER PAUL DEBONO

O B E, M D Malta, F R C S, D P H

Prof P P Debono, who died on June 3 at the age of 67, held the chair of surgery in Malta for twenty-five years, during which by practice and teaching, often in difficult circumstances, he did much to enhance the standard of surgery in the island

After graduating in 1910, Professor Debono worked for a year in London Returning to Malta he first took a teaching appointment in pathology and anatomy, and in the 1914–18 war he was associated as pathologist with the Royal Naval Medical Service and the R.A M C After the war he turned to surgery, and in 1919–22 he did postgraduate work in England, first at St Bartholomew's Hospital, London, and latterly in Manchester, obtaining the F R.C.S in 1920 In 1926 he was appointed professor of surgery and senior surgeon of the Central Hospital, Malta In 1944 he became chief surgeon of the Emergency Medical Services of Malta He retired from the chair in 1951 but continued to practise until his death In 1936–39 he had served as a nominated member of the Executive Council of Malta, and in 1947 he was elected a member of the Legislative Assembly, of which he was subsequently appointed Speaker, and served as Minister of Health

Professor Debono married Miss L Briffa in 1918, and there were two daughters of the marriage

J H S writes

I first met P P Debono early in 1943 He was still professor of surgery in Malta and working under conditions such as can never have been experienced by any senior clinical teacher before or since His " hospital " was in a requisitioned building in Hamrun a few miles outside Valletta, and it was an unsuitable place for the care of patients and particularly for those requiring surgical treatment There were other difficulties too The shortage of food and, still more, the lack of soap were the cause of skin infections that became epidemic. In the place where I

London teaching hospitals were linked with hospitals like those at Rugby, Nuneaton, and Leicester, so that nurses, perhaps at the beginning or the end of their four years, could spend one year in our provincial hospitals which at the moment were lacking nurses? Teaching hospitals had already been encouraged, said Mr WALKER-SMITH, to send their student nurses for periods of training to sanatoria and mental hospitals in particular. A compulsory arrangement of the kind suggested would be prejudicial to recruiting.

Mr E. JOHNSON asked the Minister if he was aware that there was a shortage of nurses in general hospitals, what had been the trend of recruiting during the past five years?—Mr WALKER-SMITH: While there are shortages in some hospitals, there has been a most satisfactory increase in the total numbers of nursing staff during the past five years.

The numbers of whole-time and part-time nursing staff of various grades in hospitals, other than mental and mental-deficiency hospitals, at Dec. 31, 1952 and at Sept. 30, 1957, were as follows:

	At Dec. 31, 1952	*At Sept. 30, 1957*	*Increase or Decrease*
Trained nurses			
Whole-time	32,334	36,215	+3881
Part-time	6498	10,238	+3740
Student nurses	44,932	47,128	+2196
Other nursing staff			
Whole-time	29,183	26,891	−2292
Part-time	10,678	16,591	+5913
Total			
Whole-time	106,449	110,234	+3785
Part-time	17,176	26,829	+9653

During this period the number of whole-time trained nurses at all hospitals, other than mental and mental-deficiency hospitals, increased by 12% and the number of student nurses by nearly 5%. All classes of whole-time nursing staff together increased by 3.6% and of part-time nursing staff by 56.2%.

Doctors for Colonial Territories

Mr ARTHUR BLENKINSOP asked the Secretary of State for the Colonies whether he was aware of the shortage of doctors in the Colonial Service, and what steps he was taking to encourage young doctors from Great Britain to take appointments in the West Indies and other Colonial territories.—Mr J. D. PROFUMO replied: I am well aware of the constant demand for doctors in the medical departments of the overseas territories, which the Minister is doing his best to meet. Vacancies in the West Indies and other territories are advertised in the professional journals as they are notified. In addition, special arrangements have been made to allow applications from young doctors to enter the Colonial Service as an alternative to National Service.—Mr BLENKINSOP: Will the Minister consider having some consultations with the teaching hospitals to see whether any kind of guarantee can be given to young men entering for temporary service that their chances of promotion in this country are not thereby spoiled?—Mr PROFUMO: That is something I should like to look at.

Mrs LENA JEGER: Can the Minister bring this problem more closely before the Minister of Health, who, not long ago, received a report from a committee which suggested that there should be a limitation on the intake of medical students because of the danger of the profession becoming overcrowded?

Malnutrition in East Africa

Mrs JOYCE BUTLER asked the Minister if he would consider setting up a nutrition department under the auspices of the East African High Commissioner for the purposes of food and food consumption research, diet improvement, and propaganda, and to coordinate the various activities undertaken to counteract malnutrition among children and adults in Uganda, Tanganyika, Kenya, and Zanzibar.—Mr PROFUMO replied: Coordination of such activities is already the function of the East African Council for Medical Research, under the auspices of the East Africa High Commission services, the East African Institute for Medical Research, and the East African Statistical Department. A big contribution is also being made by the Infantile Malnutrition Research Unit run by the United Kingdom Medical Research Council in Uganda with the cooperation of the local and High Commission authorities.

Obituary

ARNOLD STOTT

K.B.E., M.A., B.Chir. Cantab., F.R.C.P.

Sir Arnold Stott, who died at his home in Surrey on June 15, at the age of 72, was consulting physician to the Westminster Hospital, on whose active staff he had served for over thirty years, during which he made a name as cardiologist and general physician.

Arnold Walmsley Stott was born at Oldham in 1885, and received his early education at Rugby School. From there he went up to Cambridge, where in 1907 he took the natural-sciences tripos before going on to St. Bartholomew's Hospital, qualifying M.R.C.S. in 1909. Three years later he gained the M.R.C.P., but it was not until 1917 that he returned to Cambridge to graduate B.CHIR.

After qualifying he held a series of appointments at Bart's and the Royal Chest Hospital, and his association with the latter hospital was maintained throughout his working life. In the 1914–18 war he served in France with the rank of major. After demobilisation he returned to London, and in 1919 he joined the honorary staff of the Westminster Hospital. In 1927 he was elected F.R.C.P. During the 1939–45 war he served, with the rank of major-general, as consulting physician first to the B.E.F. and latterly to Northern Command. He was created K.B.E. in 1946. He retired from the active staff of the Westminster in 1950. At various times he examined for the University of Cambridge, the University of Birmingham, and the Royal College of Physicians of London.

As a colleague and friend, A. A. writes:

To some people, Sir Arnold Stott typified the flaneur. And yet even the least discriminating, inclined to superficial judgment, must have felt puzzled to reconcile this character with a man appointed to the Royal Household, selected as consulting physician to the B.E.F. on the outbreak of the world war, whose services were appreciated by promotion to major-general and the award of a K.B.E. The fact was that a façade of apathy and apparent indifference concealed exceptional ability.

He passed all his examinations with ease whilst displaying no interest in prizes or academic distinctions. So far from taking an M.D., he did not present the comparatively trivial thesis which at that time was a requirement for the Cambridge M.B. He was satisfied with the qualification essential for a staff appointment. Although particularly identified with cardiology, he was a general physician in the best sense of the term. The product of a worthy apprenticeship in the pathological department at St. Bartholomew's, without aspiring to brilliant diagnoses in obscure conditions, with shrewd judgment and stability in fundamentals, his opinion was always of value. For, apart from his training, he had an exceptional clinical instinct. He seldom participated at medical meetings and wrote but little. Yet these rare occasions exhibited in no small degree a gift of expression through the tongue and by the pen that others envied whilst deploring his reluctance to apply himself in proportion to his ability. Indeed ability was evident in all his undertakings whether administration in a medical school, the organisation of an Army's medical services, or the management of a dining club.

He had a remarkable capacity to stimulate and to interest without any appearance of effort. More than once this was evident in the cause of charity—for example, to assist the dependants of one who had been unfortunate. Himself indefatigable, he insisted that everybody else should be equally untiring. Loyalty was the keynote of his character: loyalty to his school, his university, his hospitals, his Lodge, and, whilst a good hater, friendship was to him a sacred trust. He fearlessly expressed his opinion in the interests of truth and justice regardless of personal consequences, through antagonising those who might adversely influence his career.

I recall an episode fully thirty-five years ago when we were the two juniors on the staff of a famous special hospital. The staff had been summoned to be addressed by an arrogant self-opinionated chairman of the hospital who had a proposition of a revolutionary character that threatened to undermine professional liberty. At the conclusion he said, “ And now I'll leave you gentlemen to talk it over. I don't wish to convince you against your will ”. Dead silence ensued, not a word from the seniors, men of eminence. Dead silence, and then Arnold Stott in a quiet clear voice, “ If you won't mind my saying so, I don't think you're particularly anxious to convince anybody about anything.” Courteous—but devastating!

Never robust, Arnold suffered frequently from attacks of bronchial infection. His last few years were clouded by almost complete disablement endured with great courage and a determination that repeatedly confounded dogmatic prognosis.

He married in 1911 Lily, daughter of Alfred Robert Holland. There were a son and two daughters of the marriage.

JOHN LAMBERT

O.B.E., M.A., M.D.Cantab., D.P.H.

Dr John Lambert, who, as medical officer to Wellington College for over a quarter of a century, became well known for his work in school medicine, died at Crowthorne, Berkshire, on June 16, at the age of 78.

He was brought up in Cambridge, and from the Perse School he went on to the university. In 1901 he obtained first-class honours in the natural sciences tripos before going to the London Hospital, from which he qualified M.B. in 1904. He held a clinical assistantship at the Hospital for Sick Children, Great Ormond Street, and later joined the Brighton Education Committee, to which he became senior school medical officer. From Brighton he went to Lancing College as resident medical officer. In 1909 he graduated M.D. During the 1914–18 war he served as a surgeon lieutenant in the Royal Navy, and for his services he was appointed O.B.E. From 1919 until 1946 he was medical officer to Wellington College, Berkshire, and to preparatory schools in the neighbourhood, at first combining the duties of medical officer and of housemaster of a waiting house.

Dr Lambert is survived by his second wife, formerly Miss Vera Pledger.

A colleague writes:

When John Lambert applied for the post at Wellington College, he impressed Dr W. W. Vaughan, then headmaster of Wellington and later of Rugby, who stands out as a judge of character, for about a score of men of his choice became headmasters of famous public schools. Lambert justified Vaughan's selection. He was noted at Wellington for accurate diagnosis, friendliness, sound advice, and imperturbability in a crisis. Soon after his arrival, he introduced an X-ray apparatus for routine use in the sanatorium, but generally he was not keen on introducing every new method.

Lambert wrote little but was proud that his predecessor, H. G. Armstrong, had been the first to describe the descent of the testicle at puberty. His own article on torsion of the testicle showed what detailed notes he kept of his patients, and his successor found his medical records of great help.

He was the most ardent attender of meetings of the Medical Officers of Schools Association, and both in council and at the general meetings spoke from his own experience and often brought an air of sanity to a discussion. He was hon. secretary from 1925 until 1936 and thereafter president until 1938. He was editor of the *Annual Proceedings* until 1947. Even after his retirement from Wellington he continued to attend very regularly.

In his early days he played cricket and golf, and he was always a most enthusiastic and successful gardener.

HENRY MANNING PEREIRA

L.R.C.P.E., D.P.H.

Dr Pereira, who died on June 11 at the age of 87, was one of that famous medical team who worked under T. F. Ricketts in the Hospital Ships and River Ambulance Service during the smallpox epidemic of 1900–02. Thereafter he never ceased to practise, and to preach, that great master's teaching on the diagnosis and the hospital management of smallpox.

Because of his characteristic modesty, to the medical world at large Pereira was probably the least well-known member of that team, but those of us who worked under him learned more about smallpox from him than from any other source, and his value, especially to medical officers of health, as a consultant—a real smallpox expert of the Ricketts school—was, of course, outstanding and almost unique.

In addition to his smallpox experience Pereira possessed an exceptional knowledge of diphtheria, enteric fever, and the old type of scarlet fever, gained from years of work in the fever hospitals of the Metropolitan Asylums Board, and when the London County Council took over those hospitals in 1930 he was appointed medical superintendent of the Eastern Hospital at Homerton, where he remained until his retirement.

Pereira was a most lovable man, supremely happy in his family life. There are many of us who will treasure the memory of his friendship.

J. P. M.

PETER PAUL DEBONO

O.B.E., M.D.Malta, F.R.C.S., D.P.H.

Prof. P. P. Debono, who died on June 3 at the age of 67, held the chair of surgery in Malta for twenty-five years, during which by practice and teaching, often in difficult circumstances, he did much to enhance the standard of surgery in the island.

After graduating in 1910, Professor Debono worked for a year in London. Returning to Malta he first took a teaching appointment in pathology and anatomy, and in the 1914–18 war he was associated as pathologist with the Royal Naval Medical Service and the R.A.M.C. After the war he turned to surgery, and in 1919–22 he did postgraduate work in England, first at St. Bartholomew's Hospital, London, and latterly in Manchester, obtaining the F.R.C.S. in 1920. In 1926 he was appointed professor of surgery and senior surgeon of the Central Hospital, Malta. In 1944 he became chief surgeon of the Emergency Medical Services of Malta. He retired from the chair in 1951 but continued to practise until his death. In 1936–39 he had served as a nominated member of the Executive Council of Malta, and in 1947 he was elected a member of the Legislative Assembly, of which he was subsequently appointed Speaker, and served as Minister of Health.

Professor Debono married Miss L. Briffa in 1918, and there were two daughters of the marriage.

J. H. S. writes:

I first met P. P. Debono early in 1943. He was still professor of surgery in Malta and working under conditions such as can never have been experienced by any senior clinical teacher before or since. His “ hospital ” was in a requisitioned building in Hamrun a few miles outside Valletta, and it was an unsuitable place for the care of patients and particularly for those requiring surgical treatment. There were other difficulties too. The shortage of food and, still more, the lack of soap were the cause of skin infections that became epidemic. In the place where I worked with one of his equally talented brothers, Prof Joseph Debono, the unfinished St Luke's Hospital, over three-quarters of the children admitted during the poliomyelitis epidemic had scabies or impetigo or both This sort of thing was enough to daunt the most ardent surgeon But Peter Paul plugged away with indomitable courage not only as a surgeon but as a teacher The men he turned out were extremely good Perhaps they were above average, but they may have gained something from having to work under such grim conditions Debono was a true general surgeon, one of the last to deserve the title, and his versatility was astonishing Nevertheless, he realised that specialisation was becoming necessary, and we talked for hours together about future developments in Malta It was not easy convincing him, but when he finally conceded a point, perhaps grudgingly, there was no going back and one could then count on his help

The Maltese Islands hold an honourable place in the history of European medicine and they have turned out men of distinction, some now working in distant parts of the Commonwealth The little medical school, shockingly housed and always short of money, is part of a university founded at the end of the sixteenth century It is easy to criticise its shortcomings, but our Maltese colleagues are even more acutely aware of them and they point out, not unreasonably, that the Government is directly responsible for the University What should not be forgotten is that men of the calibre of the Debono brothers are but three of its many notable alumni

ERNEST KEITH WESTLAKE

M A, M D Cantab, M R C P

Dr E K Westlake, a senior medical registrar at the Middlesex Hospital, who died in London last week at the age of 33, had done valuable work on chronic bronchitis and emphysema

T S, who was a senior colleague of Dr Westlake when he worked at Chase Farm Hospital, Enfield, writes

After a distinguished academic record and house-physicianship at the Middlesex Hospital, Keith Westlake became my house-physician in 1951 and later my registrar Between these two appointments he worked at the Brompton Hospital, first as a house-physician and then as a research assistant in the department of respiratory physiology Later he was registrar at the Hammersmith Hospital and senior registrar at the Middlesex Hospital He made many contributions to the literature on aspects of chronic bronchitis and emphysema, and whilst with me he passed his M R C P examination and completed his M D thesis, entitled " Disordered Respiratory Function and Carbon Dioxide Narcosis in Emphysema ", for which he was awarded the Raymond Horton-Smith prize in 1952–53 This thesis is typical of him and his work, every page reflects his thoroughness and brilliant clear thinking

He was a quiet reserved man, at times moody, difficult to know well and not given to fine speeches, and it was only on closer acquaintance that one appreciated his fine character, determination, and absolute honesty—this last was the most striking of his characteristics He had a most original and critical mind and a prodigious capacity for work He paid great attention to detail and nothing escaped his keen eye His notes were a model of accurate observation and detail—he left nothing to memory Everything had to be just right, and all doubtful observations or measurements were discarded Once his mind was set on an objective nothing would deflect him from it, and this caused people to think that he was hard—which he was not Although his approach might be called robust, beneath it all he was very sensitive and afraid of hurting people's feelings

It was a pleasure and privilege to work with him The whole hospital staff, nursing and medical alike, were fond of him and admired him for his hard work Since he left this hospital he has often been referred to affectionately by the outpatients

Dr Westlake is survived by his wife and two daughters

BERNARD SUTRO OPPENHEIMER

A.B Harvard, M D Columbia

Dr Bernard Oppenheimer, formerly chief of the medical divisions of the Mount Sinai Hospital and the Montefiore Hospital in New York, who died on June 10 at the age of 81, will be remembered by the many British postgraduate students whom he welcomed to his home One of them, D G J, writes

Dr Oppenheimer combined the qualities of an inquisitive clinical research-worker, a physician with clinical acumen, and a hospitable Anglophile He was associated with the Mount Sinai Hospital for over fifty years as physician, medical service chief, teacher, and scientist, and in 1915 he was responsible for the installation of the first cardiographic laboratory there His contribution to cardiovascular problems would be enough for any single lifetime, but typical of his drive and thirst for scientific knowedge was the way in which his retirement was deferred by the initiation of a large and continuing project on the carcinogenic properties of plastics His wife, Dr Enid Oppenheimer, an English physiologist, was his close collaborator in this programme Their weekend country home was always open to overseas postgraduates, who were encouraged, between sets of tennis, to discuss their research and clinical problems in medicine It was a poor man who came away without some new research idea, a fresh outlook on clinical medicine, and a distinct improvement in his tennis

Notes and News

MEDICINE IN CHINA

AT the annual general meeting of the Royal Society of Tropical Medicine and Hygiene on June 19, Prof A W Woodruff gave some of his impressions of medicine in China, derived from his visit last year with a group of British doctors

Setting the scene historically, he said that the traditional Chinese philosophy had hitherto been one of respect for antiquity and rejection of change, but politically the last century had been marked by corruption, civil war, widespread poverty, and foreign invasions In 1948, the change of regime brought a revolution of ideas, as well as the massive political revolution, which completely reversed the ancient conceptions and trends The industrial revolution was initiated and had been accepted with fervour Part of the Government plan was a comprehensive medical scheme which, though not yet completed, was the eventual goal. But China had fewer qualified doctors than Britain, for a population more than ten times as great, though in rural areas there were large numbers of traditional practitioners sometimes skilled in the use of herbal remedies and full of the kind of unscientific mysterious authority so often found among medicine men in backward countries The authorities made use of these men, gave them some form of instruction in scientific medicine whenever possible, and, instead of antagonising them, drew them into the general organisation. But their day would end, and the output of fully trained medical graduates from the 32 colleges which now give five-year courses (soon, it was hoped, to be made six-year courses) would gradually provide the required numbers The standard in these colleges was high, though to British observers the time spent in studying dialectical materialism seemed excessive.

Postgraduate medical education was conducted at the great Peking Medical College, and here again the standard was high There were various research institutes in Peking, Shanghai, and other places, and the subjects for research included epidemic diseases, industrial diseases, public health, traditional medicine, and specific Chinese problems At Shanghai the enormous problems of *Schistosoma japonicum* infection (11 million people were affected, most of them in the Yangtse valley) were being tackled This disease was taken so seriously, and the treatment and control measures were on so large a scale, that Professor Woodruff thought that it would be overcome more quickly than in other countries where it was endemic

In Chinese cities there were now few dogs and few flies, and it was the mark of a good citizen to be diligent in destroying both, it was therefore equally the mark of a bad citizen to be indifferent, and a bad citizen might have a bad time. The streets and the people were clean, and cleanliness, order, and health were popular The former poverty had largely passed away, partly because the Government gave incentives to production, and the old stranglehold of the moneylender had gone. The Government had established the rule of law, stabilised the currency, and started great schemes of reconstruction and industrialisation which would increase wealth and which were popular they were needed for a population growing at a fantastic rate

The price exacted from the people for these undoubted material rewards was conformity, and this was now given with enthusiasm China might soon be the most powerful nation in the world, and we might hope that the traditional Chinese talent for compromise would lead to a system more tolerant than that of Russia China might look to the West if the inducement was strong enough One way in which the West could encourage such a tendency would be by offering training here for young Chinese graduates in the methods and ideals which we found acceptable Professor Woodruff's message was that Europe and the West should make a vital constructive effort of friendship towards this serious, progressive, and rapidly developing people, for whom we have always had warm regard

INADEQUATE DIETS IN PREGNANCY

LAST year there was a noticeable deterioration in the diets of many women, according to Miss Helen Simpson, dietitian to the Simpson Memorial Maternity Pavilion of Edinburgh Royal Infirmary Miss Simpson, in her report on 1957, says that the deterioration was due chiefly to the slightly increased cost of living and to the higher incidence of unemployment In some cases, although the income appeared to be adequate, hire-purchase commitments upset the balance of the budget Protein foods, being the most expensive, were reduced, and more carbohydrate was eaten to satisfy the appetite The special pint of milk provided at half price for a pregnant woman was often shared with the family Less fruit and vegetables were bought when less money was available The result of this was evident in the increasing number of young women found to be anæmic Many women who were apparently in good health at the beginning of pregnancy quickly became anæmic later In addition to iron therapy, dietary investigation and advice were helpful in these cases

NATIONAL ASSISTANCE BOARD

THE report [1] of the Board for 1957 shows that the number of weekly allowances rose during the year by 56,000 to 1,712,000 (covering the needs of nearly $2^1/_2$ million people) The cost of assistance was £112,200,000 Nearly three-quarters of the 1,712,000 allowances went to supplement national insurance benefits, including 978,000 to supplement retirement pensions and 118,000 to supplement sickness benefit or industrial-injury payments Nearly $1^1/_4$ million of the people receiving allowances were over pensionable age.

Between October, 1956, and the end of March, 1957, about 21,000 people from Hungary sought refuge in this country, and at the peak of activity the voluntary organisations, which undertook the task of receiving them, were using well over a hundred establishments to house them. About 5500 emigrated, mainly to Canada, and others were quickly settled in work and found private accommodation But many still needed room—and often free maintenance—in hostels, and when the money available from a fund raised by the Lord Mayor of London was exhausted the cost of running the hostels was borne by the Exchequer, and the Board took over administration from the British Council for Aid to Refugees on Oct. 1 At that date there remained twelve hostels with 1814 residents, by the end of 1957 two more hostels had been closed and the number of residents reduced to 1427 The net cost to the Board for the three months was about £44,000

BILLY GOES TO HOSPITAL

THIS lively coloured picture-book which the departments of child health and medical illustration of Guy's Hospital have combined to produce should do much to reassure any small patient-to-be In appearance it is cleverly reminiscent of one of the pleasanter weekly comics, and it is full of the everyday details which children enjoy A five-year-old who has studied it on his mother's knee will find a hospital ward welcoming and familiar instead of strange and alarming The enclosed leaflet for parents offers sensible advice about preparing a child for his stay in hospital and explains his special need for visits, small gifts, and postcards while he is there, and for extra affection and care when he returns home

On another page of this issue Prof R. S Illingworth mentions some of the hospitals which have already prepared booklets of this kind for their young entrants, and he asks for more Guy's booklet certainly gives his appeal a flying start

AN ATTRACTIVE SANATORIUM

TUBERCULOSIS is more than a disease it is a philosophy And, like other philosophies, it has its distinctive bibliography (*The Magic Mountain* and *The Plague and I* are two examples) The author of a new novel,[2] *At Doctor Mac's*, may have more in common with Betty McDonald than Thomas Mann, but he has nevertheless made a notable addition to this series

---

[1] Cmnd. 444 H.M Stationery Office 3s

[2] At Doctor Mac's By PETER QUINCE London J M Dent. 1958 Pp 277 15s

Doctor Mac's is a private sanatorium, maintained by a kindly physician whose only interests in life are tuberculosis and music His establishment may be run along unconventional lines, but it accomplishes the cure of some difficult cases—patients with emotional as well as physical disturbances Though there is no Peter Quince in *The Medical Directory*, the book has an authentic ring, and its readers will not be surprised to learn that the author has practised both as psychiatrist and chest physician

Doctors, of course, are far from enjoying professional immunity to tuberculosis (Laennec and Withering, Trudeau and Ehrlich, were all constrained to take more than an objective interest in the disease) And every doctor will say to himself, when he has finished this book, "If ever I have to go to a sanatorium, let it be one like Doctor Mac's!"

FILMS ON CARDIAC ARREST AND MASSAGE

SOMETIMES in sudden cardiac arrest transthoracic cardiac massage is either not carried out or postponed while less effective procedures are tried, owing to hesitation to enter the chest, coupled with lack of preparation for such an emergency

A film on *Respiratory and Cardiac Arrest* (16 mm , sound, black-and-white, 15 min , 1945) [1] was made by Dr Geoffrey Organe and Dr I W Magill at Westminster Hospital Though much of the film is still accurate, details of the procedure have since been changed

Dr Claude S Beck has made several films on the subject, his most recent one, *Resuscitation for Cardiac Arrest* (16 mm , sound, colour, 18 min , 1956),[2] is the best at present available

Dr Beck, who delivers a filmed lecture, divides his objectives into restoration of the oxygen system and re-establishment of the heart-beat The emergency lasts until the first has been achieved, and time should not be wasted listening for heart-sounds, taking an electrocardiogram, injecting adrenaline, dilating the anal sphincter, and so on The routine should consist of oxygenation through an endotracheal tube and direct cardiac massage through a submammary incision The second stage can be more leisurely The method of performing cardiac massage is demonstrated on a dog's heart, and a series of pressure tracings show the efficacy of different grasps on the heart and the importance of allowing adequate filling between each compression

A short film on *Cardiac Massage* (16 mm , mute, colour, 2 min , 1956),[1] was made by Mr B B Milstein at the Brompton Hospital, London This is primarily a demonstration of the surgical approach to the heart, and the method of cardiac massage with the pericardium intact, through an incision in the pericardium and finally by bimanual compression of the heart It was made to illustrate a lecture on the subject and is thus less complete than the other films

A new film, *Cardiac Arrest* (16 mm , sound, colour, 17 min , 1958) [1] by Dr John Beard was shown at a recent meeting of the Faculty of Anæsthetists at the Royal College of Surgeons of England

It opens with a lecture by Dr Beard on the role of anoxæmia in cardiac arrest A man is then seen to collapse in an outpatient department The technique of cardiac massage is demonstrated on a rubber heart, and the difference between arrest and ventricular fibrillation is shown on an electrocardiogram The patient is given oxygen from an anæsthetic machine, and, since the carotid pulsation is absent and the pupils are dilated, a pharyngeal airway is inserted

An attendant takes over the positive-pressure respiration while the doctor incises the chest in the fourth left interspace, spreads the ribs, and applies cardiac massage On the arrival of the surgeon, the first doctor returns to the head of the table and inserts an endotracheal tube The second half of the film is devoted to a discussion on methods of restoring the heart-beat Finally, mention is made of the intravenous injection of 50% sucrose solution if recovery is delayed

Royal College of Physicians of Edinburgh

The William Cullen prize, awarded by the college every four years " for the greatest benefit done to practical medicine ", has been awarded to Dr W Melville Arnott, professor of medicine in the University of Birmingham

University of Bristol

At recent examinations the following were successful

M D—H M Leather, Henry Urich

M B , Ch B—R T Marcus, Michael Nicholas, R A Sharpe (second class honours), R A R Abraham, Daphne M Allen, Sarah M Brewer, Barbara A Brooking, John Brunning, R A Bunting, J B Burchill, Mervyn Busson, Joan R Coombs, T O Dada, Philip Dent, S V C Egonu, C C Entwistle, P T Gardner, R A G Huish, G H Hulands, F W Lewis, Susi G Leyton, Alison J McConnell, Yvonne E J Marot, B S Milner, C D Murphy, V P Nagpal, E O Olurin, Glenys R Packer, M I eM Parker, M P Patel, A P C H Roome, M H Seymour, F D Skerrett, J M Slater, Ivor Surveyor, Lip Hing Thean, Umathevan Viswalingam, J T Ward, Juliet M Whitehead, Mary G Wilmot

University of Edinburgh

The following appointments have been made

Mr J J Mason Brown, reader in pædiatric surgery, Dr R H Girdwood, reader in medicine, Mr G D Matthew, reader in obstetrics and gynæcology, Dr W N Morley, assistant in medicine, Dr R S Nagle, lecturer in pathology

University of St Andrews

Dr R E Coupland has been appointed to the Cox chair of anatomy in succession to Prof D Rutherford Dow, who retires on Sept 30 The department is in Queen's College, Dundee, and Dr Coupland will be a member of that college

Dr Coupland, graduated M B with honours at Leeds in 1947, thereafter gaining the M D in 1952 and the PH D in 1954 Following a house appointment in surgery at Leeds General Infirmary, Dr Coupland acted as demonstrator in anatomy at the university, and, after National Service with the R A F , he returned to Leeds in 1950 as lecturer—the appointment which he holds at present He spent a period during 1955–56 in the department of anatomy, University of Minnesota, as assistant professor For some years Dr Coupland has been interested in research into adrenal function and specially the distribution and function of chromaffin tissue He has also worked on the transplantation of endocrine organs and on the histochemistry of the autonomic nervous system He will take up his appointment on Oct 1

University of Dublin

At a recent examination the following were awarded the diploma in gynæcology and obstetrics

F C Das, Gauri Deb, Azima Iqbal Qureshi, Sarah Ramachandran, I Raychaudhuri, S Sarkar

European Society of Hæmatology

This society will hold a congress in Bedford College, Regent's Park, London, N W 1, from Sept 7 to 12, 1959 It will be organised by the British section of the society under the presidency of Dr J F Wilkinson Further particulars may be had from the secretary, Dr Ernst Neumark, department of pathology, St Mary's Hospital, W 2

W H O Executive Board

The Executive Board of the World Health Organisation met in Minneapolis, Minnesota, on June 16 and 17, under the chairmanship of Dr Percy Moore (Canada) The Board established a special account to deal with gifts of smallpox vaccine offered by governments to assist in a smallpox eradication campaign The Board established a committee to be available for consultation with W H O 's director-general in his further negotiations with the International Atomic Energy Agency with a view to concluding an agreement between the two agencies

From July 1, under the National Health Service Contributions Act, 1958, the weekly contribution for the National Health Service will be increased by *6d* for men, *4d* for women, and *2d* for juveniles, with an additional *2d* from the employer in the case of employed persons The new combined weekly rates of National Insurance and National Health Service contributions are set out in leaflet N I 103, obtainable at Pensions and National Insurance offices

CORRIGENDUM *Carnegies Emergency Solution of L-Noradrenaline*—This is made up in ' Snapules ' containing 0 2 mg in 2 ml , and not 2 mg in 2 ml as was stated in last week's advertisement (p 4)

Births, Marriages, and Deaths

DEATHS

LAMBERT —On June 16, suddenly at Crowthorne, John Lambert, O B E M A , M D , late medical officer of Wellington College, aged 78
